Alternative Methods.—The preceding discussion does not pretend to be exhaustive, and certain alternatives to the methods described are possible. Thus we might devise an alternative to the $4n$-ordinate method by erecting ordinates y_1, y_2, y_3, &c., at the respective distances $\pi/6n$, $5\pi/6n$, $7\pi/6n$, $11\pi/6n$, $13\pi/6n$, &c., from the origin. Twice the average of these ordinates with signs reversed in pairs according to the scheme $++--++$&c., gives $A_n+2A_{3n}+A_{5n}-A_{7n}-2A_{9n}-A_{11n}+A_{13n}+$ &c. By taking the arithmetical mean between this result and that given by Fischer-Hinnen's $2n$-ordinate method (thus utilising $6n$ separate ordinates), we obtain $A_n+\frac{1}{2}A_{3n}+A_{5n}-A_{7n}-\frac{1}{2}A_{9n}-A_{11n}+A_{13n}+$&c. To get the corresponding cosine terms a new set of ordinates y'_1, y'_2, y'_3, &c., must be erected at successive distances $\pi/3n$, $2\pi/3n$, $4\pi/3n$, $5\pi/3n$, $7\pi/3n$, &c., from the origin. Twice the average of these ordinates with signs reversed in pairs according to the scheme $+--++--$&c., gives $B_n-2B_{3n}+B_{5n}+B_{7n}-2B_{9n}+B_{11n}+$ &c., and by combining this with the corresponding result obtained by the $2n$-ordinate method we have $B_n-\frac{1}{2}B_{3n}+B_{5n}+B_{7n}-\frac{1}{2}B_{9n}+B_{11n}+$ &c.

Another way of treating the ordinates drawn as indicated in the last paragraph is to average y'_1, y'_2, y'_3, &c., with signs reversed in pairs according to the scheme $++--++$ &c. This average, when multiplied by $2/\sqrt{3}$, gives $A_n-A_{5n}+A_{7n}-A_{11n}+A_{13n}-$&c., or, combined with the $2n$-ordinate method so as to utilise $6n$ separate ordinates, $A_n-\frac{1}{2}A_{3n}+\frac{1}{2}A_{9n}-A_{11n}+A_{13n}-$&c. Similarly, $2/\sqrt{3}$ times the average of y_1, y_2, y_3, &c., with signs reversed in pairs according to the scheme $+--++--$&c., gives $B_n-B_{5n}-B_{7n}+B_{11n}+B_{13n}-$&c., or, combined with the $2n$-ordinate method, $B_n+\frac{1}{2}B_{3n}+\frac{1}{2}B_{9n}+B_{11n}+B_{13n}+$&c.

Evidently both of the "combined" or $6n$-ordinate methods thus obtained are inferior to the $6n$-ordinate method previously described, since the results they give contain a larger number of included harmonics. In this respect the second of the alternative $4n$-ordinate methods is, however, superior to the $4n$-ordinate method referred to in an earlier part of the article, as also to Fischer-Hinnen's $2n$-ordinate method. Thus the ascending order of accuracy as estimated by the number of included higher harmonics is (i) Fischer-Hinnen's $2n$-ordinate method, (ii) the second of the alternative $4n$-ordinate methods, (iii) the $6n$-ordinate method first described.

THE ORIGIN AND PRODUCTION OF "CORRUGATION" OF TRAMWAY RAILS.*

BY W. WORBY BEAUMONT.

Summary.—The author calls attention to the various stresses which are set up in free flat bars of iron and steel when subjected to rolling or hammering, and that this originates on the upper surface of the rail a condition of intense compressive stress, tending to produce a modification of form. The results of tests made on the L.C.C. tramways and other systems are given.

Few of the phenomena of the behaviour of materials employed in tramway construction have given rise to so much enquiry, speculation and diversity of opinion in the last few years as the phenomenon known as "corrugation" of tramway rails.

The rapid spread of its occurrence in nearly all towns with heavy tramway service has directed anxious attention to the discovery

* Paper read before Section G (Engineering) of the British Association at Portsmouth.

Digitized by Google

of its cause, and much has been written concerning it, and some experimental investigations have been made. Unfortunately, the indoor experiments have seldom been conducted with apparatus or under conditions which simulate those of the tramway itself.

On the other hand, the observations which have been made by many on the rails themselves have led to every possible variety of interpretation of the cause of corrugation, largely because of the apparent contrariety of its occurrence and non-occurrence.

The author had commenced the preparation of an index to the Papers and articles which have appeared in this and other countries during the past five years, but it was soon found that this would be of intolerable length, and after all of but little service. The "Proceedings" of the Institution of Civil Engineers provide abstracts of Papers too numerous to mention; the Institution of Electrical Engineers has dealt with the subject; the Municipal Tramway Association and the Tramway Congress hardly ever meet without dealing with the subject; the Tramways and Light Railways Association Official Circular and "Journal" for some years has been crowded with corrugation inequalities and vagaries, and lately a Joint Committee of the two Associations—the Municipal Tramways Association and the Tramways and Light Railways Association—has been working on the subject. To the proceedings of this Committee the author has contributed, and had previously dealt with the subject elsewhere. Foreign authors have contributed largely, and a report by a Committee consisting of the managers of nine Continental tramway systems, one British professor of engineering and the secretary, was discussed at the International Tramway Congress held in Brussels in 1910.

One of the recent and most useful reports on the subject (although some judicious analysis of the facts presented is required) has been prepared as a provisional report by a Committee of the technical department for railway construction and exploitation of Amsterdam, including Messrs. J. Schrooder van der Kolk, M.P., Mass Geesteranne and T. E. van Putten. And more recently a Paper by Herr Von Borries, of much merit, has been published.

Having given some attention to all this literature of this particular

Fig. 1.

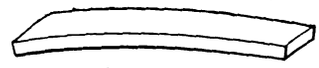

Fig. 2.

engineering ailment, and being aware of the indecision that still exists in the minds of many upon it, the author now ventures, at more length and with the object of greater precision, the explanation he has on previous occasions attempted to convey.

The subject has hitherto been treated mainly from the general point of view suggested by the practical experience of the tramway manager and engineer, and has seldom attracted or received the considered reasoning conjointly of the mechanic and the physicist. It is, however, one which in a marked degree demands the patient application of the attributes of both, and in this Paper I may repeat the words of Mr. H. R. A. Mallock,* and say "it is often useful to have a simple, even if incomplete, theoretical treatment of a subject provided that the theory is correct as far as it goes, and is kept within bounds by comparison with actual observations."

In a surface of a homogeneous solid under compressive stress in orthogonal directions in the plane of the surface, every particle tends to cause every particle surrounding it to recede in every direction.

If one surface of a free flat bar of steel or iron, as Fig. 1, be rolled or hammered, the material of that surface is subjected to a compressive stress. Of this stress it is relieved in the direction of length of the bar so far as the stress is no greater than that which is necessary to bend the bar, and cause it to keep the bent form of Fig. 2.

If of wrought iron, the molecular surface stress will in part be relieved by flow of the material or detrusion along the edges of the hammered surface, and the longitudinal bending be less than if the bar be of rail steel, in which the detrusion will be less.

If of cast iron, the surface compressive stress will accumulate and the bar will be bent by it; but the accumulation of stress reaches an early limit, as it sooner exceeds the limit of cohesion between the surface and subjacent material. The result is that, with cast iron, surface crumbling occurs and limits stress accumulation. It does, however, become sufficient to permit its use as a means of straightening cast-iron coping plates and the like if slightly curved when taken out of the sand.

If when a bar has been bent by surface compression of one side, it be forcibly straightened, the compressive stress will be increased, and a tensile stress impressed on the opposite side sufficient to eliminate the difference of dimension of the two sides caused by the compression. To remove the difference permanently the stress on the uncompressed side must reach the character of strain, equally distributed throughout the whole length of the bar. At the same time an increase is made in the compressive stress on the rolled or hammered surface. This cannot be relieved by a single pucker or extrusion of the surface about the centre of length of the bar, as the stress is uniformly distributed. Hence, at distances apart (or pitch), depending on the elastic and cohesive properties of the material, there will result incipient surface crumblings or corrugations, as shown exaggerated in Fig. 3.

The bearing of this fact on the tramway or railway rail will appear hereafter, but here it may be observed that the stresses in a bar which is bent by compression of one side and caused to retain the bent form by that resident molecular stress, is not in the same condition as to stress throughout its structure as a similar bar bent and maintained in a bent form by mechanically imposed distributed load.

Fig. 3.

In the bar bent by compression of the material on one side there is molecular tensile stress immediately below the hammered surface. The compression differentiates in intensity from the surface to a zone or couche under tensile stress resulting from the molecular cohesion which has prevented the compressed and extended surface from separating itself by shear. Below this, tensile stress differentiates into a neutral zone and therefrom into the compressive stress which remains resident in the bar so long as it is bent by these internal forces.

In a surface such as that of an ironplate which has been rolled or hammered on that surface only, the particles of the hammered surface are, as previously mentioned, restrained by cohesion of and with the subjacent particles, which are less and less under compression as they are remote from the compressed surface film.

If any two points, *a*, *b*, or *a'*, *b'*, Fig. 4, be taken in such a surface film, it will be seen that all the particles round each point press towards it with forces proportional to some function of their respective distances from such points. In a line drawn from *a* to *b*, or *a' b'*, there are, therefore, equal and opposite forces tending to separate those points, and when their amount exceeds the elastic resistance of the material, deformation or crushing or crumpling

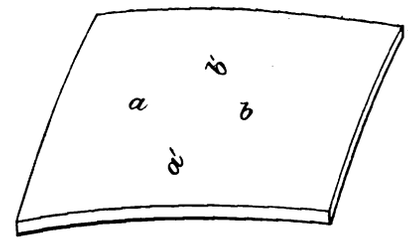

Fig. 4.

must occur, if change of form of that of which the surface is a part be restrained. If the surface be that of a deformable plate, then the forces are in part relieved by bending the plate in orthogonal directions. It is not necessary here to determine the distance between *a* and *b* at which any given material will reach the yielding point, or at which the accumulated forces will be sufficient to cause either the bending of a plate or give rise to destructive stresses in any other form of which the compressed surface is part.

To this a return may be made later, but here it is sufficient to repeat that it will be dependent upon the relation between the elastic resistance of the material to compression and its elastic tensile strength and its hardness.

In dealing with these stresses as occurring in practice, and in such forms as those of a railway or tramway rail, it will be seen from the foregoing that the values of the stresses in orthogonal directions soon reach inequality, because while they become cumulative in the direction of length of the rail, the distance transversely separating the points *a* and *b* earlier reach the limits of dimensions at which the forces can arise, because relief of the stresses is found in lateral deformation or detrusion at the rail edges, as in Fig. 5.

There is a further view of the physical conditions to be considered, which under the mechanical conditions of the rolling of a wheel on

* "Proc." Inst. Civ. Eng., Vol. CLXXVIII., 1909.

Digitized by Google

the plane surface of a rail under pressure greater than or approaching its elastic resistance gives rise to that which results in what is known as corrugation.

A loaded circular surface, as of a roller or wheel resting upon a deformable straight plane surface, has but a line contact with that surface until either or both the circular and flat surfaces of contact are so deformed by loading the roller as to increase the area of contact. The deformation will continue until the resistance to deformation equals the force producing it. If the materials of the two surfaces be equally resistant, the circular surface will be flattened and the flat surface will be depressed or indented. If the roller be of the more resistant material, the deformation may be chiefly in the material of the flat surface. If the roller be made to roll along the surface which it can so deform it presses before it a wave of deformation. The depression giving rise to this wave may (as in the case of the tramcar wheels and rails) approach or exceed the limit of elastic deformation of the material of the rail. When this is the case, continuation of the movement of the roller upon the surface demands

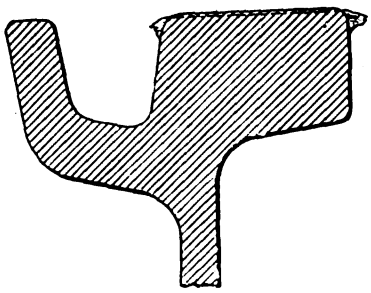

FIG. 5.

the translation of the crest of the wave, and this would involve the destruction of the cohesion between the rolled compressed surface wave crest and the material supporting it and of which it is a part. The result, therefore, is that tensile stress arises *pari passu* with the wave formation between the wave particle and the subjacent particle of the material supporting it, and the point is reached at which the tensile resistance to the increase of the wave height prevents further increase. The roller then must rise upon the minute crest, and in doing this with its heavy load upon the extremely small area compresses it to extreme hardness.

The roller (wheel) in its continued progress repeats the process and continuously adds to the rearward dimensions of the hardened spot.

The foregoing then shows that the rolling and hammering of the upper surfaces of a rail originate a condition of intense compressive stress, the elimination of which produces, or tends to produce, modification of form. It also shows that areas of maximum compression are originated at points separated by distances which are determined mainly by the relation between compression resistance and elastic strength of the material rolled, but in part by the relative hardness of the roller and rail and by the mechanical conditions which affect the area of the roller and rail contact.

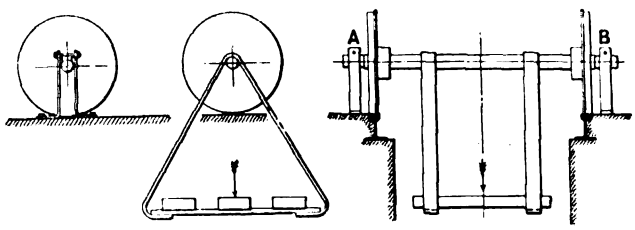

FIG. 6.—AREA OF CONTACT OF TRAMCAR WHEELS ON RAILS.
(Experimental Apparatus.)

The area of contact of hard tyre tramway wheels on steel rails is very small—is less than on ordinary railway wheels. On the latter it has been found to vary, with wheels 4 ft. 6 in. to 5 ft. in diameter, and carrying a steadily applied static load of from 12,000 lb. to 14,000 lb. per wheel, from 66,000 lb. to 48,000 lb. per square inch of contact area. The minimum and maximum areas of a larger number of observations gave loads per square inch of contact area of from 26,607 lb. to 85,961 lb. This, however, was the minimum pressure, as it was taken with engines standing on a level rail and the wheel gently lowered on to it. With an engine moving at speed and healing over as on curves, this pressure would be much greater. It must further be noted that the central part of the area of contact would be much more severely pressed than the borders of the area.

By the courtesy of Mr. A. L. C. Fell, M.I.E.E., the author has been enabled to give measurements made at his request of the pressure of the wheels of a standing car on rails of standard type. These measurements were made by loading the axles of the larger and the smaller wheels of the bogie of one of the large standard London County Council double-bogie trucks.

For the purpose of the experiments, a sling was made as shown in the diagram Fig. 6. This consisted of flat bars to which were bolted three pieces of timber on which the load was placed. The rails were carefully cleaned and the wheels turned to the correct standard taper, but with a finer cut than that usually adopted in practice.

The load used was as follows in each case :—

Driving wheels, 31 in. diameter, 6 tons.
Pony wheels, 21·56 in. diameter, 3·25 tons.

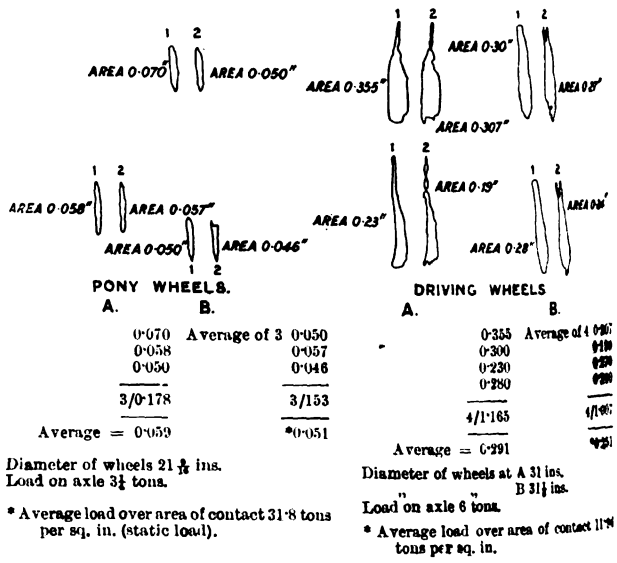
These weights approximate closely to the actual weights on a standard bogie car when loaded.

The wheel on the side marked A, *see* Fig. 6, was on the rail where it was continuously supported. On the side marked B the wheel rested immediately above the centre of a pier 14 in. wide, where the rail was not quite so rigidly carried. The diagrams obtained, marked 1 in Fig. 7, were slightly larger on this side.

The rails showed very little sign of wear, and the experiments were made at the end of a shop which has not been very much used. At each end of the axle a guide bracket was fixed to the ground, as shown in Fig. 6 ; between these brackets and the axle journal taper pieces of wood were fixed to prevent lateral movement.

The axle was lifted at the extreme end by means of a jack, and lowered carefully on a piece of tissue paper on thin carbon paper placed on the rail under the wheel. The impressions made are shown by the diagrams herewith (*see* Fig. 7).

The rails were of British standard hardness, and the tyres were manufactured to specification, for the following extract from which the author is indebted to Mr. Fell.



Diameter of wheels 21 $\frac{5}{16}$ ins.
Load on axle 3¼ tons.

* Average load over area of contact 31·8 tons per sq. in. (static load).

Diameter of wheels at A 31 ins.
" " B 31¼ ins.
Load on axle 6 tons.

* Average load over area of contact 11·8 tons per sq. in.

FIG. 7.—DIAGRAMS OF CONTACT AREAS.

Tensile strength not less than 55 and not more than 70 tons per square inch, minimum elongation of 11 to 8 per cent. in 2 in., and of the following composition :—

Carbon	0·65 to 0·75 per cent.
Silicon	0·32 "
Manganese	0·6 to 0·8 "
Sulphur	0·035 "
Phosphorus	0·035 "

The tyres are thus of harder material than the rails, which have 0·40 to 0·55 per cent. carbon.

The areas of contact carefully measured from these diagrams are given on the drawings accompanying this Paper, the areas and pressures given being those obtained from the smaller diagrams marked 2 measured on the inner edge of the black lines made by the carbon paper. The loads given per square inch are the average loads over the whole area of the diagram when the tyre had pressed into the rail, and the tyre itself also microscopically deformed until the area of support given was obtained. The pressure per unit of area in the centre of the area of support would, of course, enormously exceed this average, and I estimate the maximum static pressure to be not less than 35 tons per square inch under this driving wheel. When the car is running at ordinary speeds the pressure would rise to not less than double this as impact pressure, and when the car runs at speed round curves, and the greater part of the load with the heeling over of the car is visited on the wheels on one side, the pressure might easily reach at least 100 tons per square inch.

Digitized by Google

On the pony wheels the average pressure of the whole area of contact under static loads reached 31·8 tons per square inch. The maximum pressure in the centre of area of contact was probably not less than 50 tons. This, with the car running at ordinary speeds, would probably reach 90 tons per square inch, and when running at speed round curves and the car heeling over so that the greater part of the load rested on the wheels on one side, the maximum pressure would probably reach 120 tons per square inch.

It is clear, then, that the pressure per unit of area much exceeds the limit of elastic compression of the material of the average rail, and that flow or deformation would occur were it not that the area pressed is supported by the surrounding material and held *encastrée*, so that flow cannot occur. One result of this is the detrusion of one or of both the rail edges, as shown by Fig. 5, by which cumulative

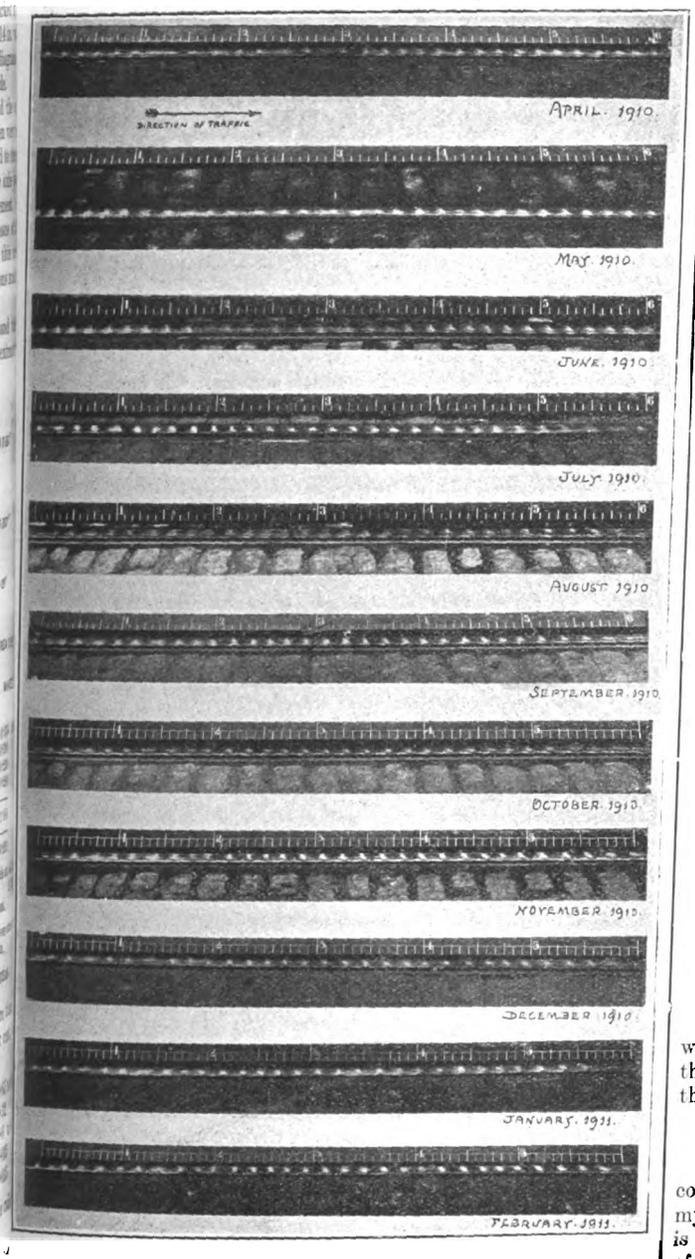


FIG. 8.—LEEDS CITY TRAMWAYS.—PARK LANE.
38 ft. 6 in. past pole 20. Outgoing track. Outer rail. Straight track. Down gradient 1 in 70. Pitch of corrugations, 2 in. In use 10 years. Section No. 6, L.S.W.

disruptive forces are in part dissipated and the extruded material on the groove edge of the tread is removed by the car wheel flanges. Another result is corrugation, and a third is the minute crumbling and pitting of the rolled surface.

Under some circumstances and conditions corrugations may decrease as the raised hardened surfaces approach by lengthening; and as corrugation and the surface become more uniform by the removal of surface material by crumbling or minute flaking, especially of the harder rails with up to 0·66 of carbon, which best resist the causes of corrugation. The removal of corrugations, however, by grinding only prepares the rail surface for quick recommencement of corrugation or for lengthening the hardened part of the corrugations.

If the preceding be accepted as the origin and production of corrugation, then the question remains, What are the remedies? The mechanical originating conditions being the weight on the wheels and the increase of that weight, more especially on outside curves by car heeling at the higher speeds, then:—

The first and most effective remedy is the reduction of the great destructive weight on the wheels of the modern car.

The second is the use of larger wheels than can be used with the present design of car.

The third is the maintenance of moderate speeds; of much lower speeds than are common on curves even those of large radius, and moderate speeds on lines that may be classed as straight, but which have such departure from straightness as will encourage boxing or wandering of the cars from side to side.

Fourthly, the use of harder rails than the hardest at present employed.

The reduction of weight is possible, the reduction of speed is possible, the use of larger wheels is possible with future cars, and the use of harder or more resistant rail materials may be possible, but they would have to be produced by methods more costly than those now adopted. The remedies will involve modifications in the views at present prevalent as to the place, purpose and working of tramway services; but even the most ardent advocates of tramway ubiquity

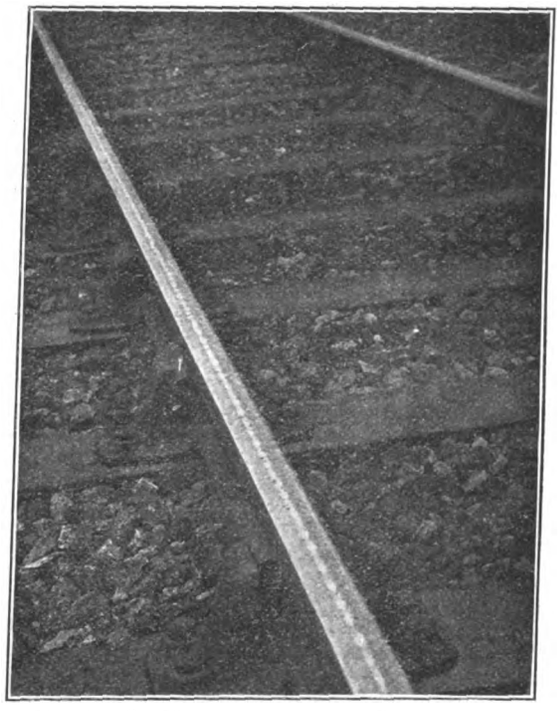

FIG. 9.—ON MIDLAND RAILWAY.—SHEFFIELD.
Straight track. Falling gradient of 1 in 100.

will ultimately be constrained to admit that tramways, like all other things that have and offer desirable ends and convenience, have also their economic and expediency limits.

ADDENDUM.

The occurrence of corrugation of electric tramway rails, as recorded by many tramway engineers and managers, and as found by my own observations extending over some years at home and abroad, is everywhere associated with the following broad generalisations of facts:—

1. That it occurs on straight lines and on curves.
2. That it is most prevalent and generally commences on curves of large radius—flat curves.
3. That it never or rarely occurs on curves of small radius—*e.g.*, from 40 ft. to 80 ft.
4. That on hills, and especially on slight gradients, it is most prevalent on the down line.
5. That its occurrence as to date or length of time after laying the rails varies broadly with (*a*) the position of the rail on straight or flat curve or down gradient, (*b*) the frequency of the service, (*c*) the mechanical properties and composition of the rails, as shown by more or less outer edge detrusion.
6. That it occurs with all types of truck.
7. That it is most prevalent where the speeds are highest.

Digitized by Google

The general appearance of corrugated rails is known to all who are interested in the subject, and photographs showing corrugations in various stages of growth in many towns might be shown. The author is enabled, by the courtesy of Mr. J. B. Hamilton, general manager of the Leeds tramways, to show photographs of three sets of 33 rails in that city. These photographs show rails which have been in use from 4 to 13 years on straight track. Those which have been in use 13 years are on the level, those of 10 years (*see* Fig. 8) are on a gradient of 1 in 70, and those which have been in use four years are on a gradient of 1 in 50.

A small photograph, Fig. 9, is exhibited of a rail in a straight piece of track on the Midland Railway, Sheffield, on a falling gradient of 1 in 100. This shows a much worn rail, with the bright hard spots about the centre of the tread, and shows that what is called corrugation is not confined as to nature of origin or production to street tramway rails, although it is necessarily much more general and severe on tramways and other rails where heavy vehicles with small wheels and high speeds are used, as, for example, on some of our tube lines and the Metropolitan of Paris.

RECENT DEVELOPMENTS IN RADIO-TELEGRAPHY.*

BY G. W. O. HOWE, M.SC.

Summary.—The author first discusses the difficulties experienced in wireless transmission due to interferences, atmospheric disturbances, &c. He then considers recent developments for minimising such interference and improving the conditions, dealing firstly with the transmitting apparatus, and secondly with the receiving apparatus.

During the last two or three years the number of radio-telegraphic installations has increased enormously both on land and sea. This increase has not been due so much to any new discovery or striking improvement as to several instances in which radio-telegraphy prevented what might otherwise have been terrible calamities at sea.

The total number of ships of the mercantile marine fitted with Marconi apparatus at the end of 1907, that is, after seven years of development, was 140; at the end of 1908 the number was 220; at the end of 1909 it was 330, while at the close of last year it had risen to 510. In addition to the mercantile marine, practically every ship in the British navy has been fitted with Marconi apparatus.

The Telefunken Company, of Berlin, carried out 106 installations last year, bringing the total number of stations using their apparatus up to nearly 1,000. About 500 of these are warships, principally German and Russian, while 100 are portable military sets. Excluding German boats, only 13 ships of the mercantile marine are fitted with Telefunken apparatus.

Marconi's earliest experiments were made in 1895–1896 and now, after 15 years, every passenger ship of any magnitude has its wireless installation as a matter of course. There is every indication that very soon practically every ship will be so equipped. Some of the trawlers of the North Sea fishing fleet have recently been fitted with Telefunken apparatus with a range of about 100 miles. These boats receive the weather reports sent out daily from the coast stations and are thus able to warn the fleet of approaching storms.

As was recently pointed out by Mr. Bradfield of the Marconi Company the increase in the number of installations will probably be cumulative, since each installation on land or sea increases the value of the service to every ship making use of it. There is, however, another aspect to which attention should be drawn, and that is, that the troubles due to interference between stations working simultaneously will also increase cumulatively. These troubles promise to become of the gravest importance in the immediate future.

Before one can appreciate the recent developments in the apparatus, one must know something of the difficulties experienced in carrying on radio-telegraphic communication. The nature of the telegraphic service which may be required of a station is very varied. A station may have to work with only one other station and never send to, or receive from, any other. This is practically the case with the trans-Atlantic stations. A station may correspond with a limited number of stations with definite and well-known characteristics as in the case of the mail-boats running between England and the Continent. On the other hand, a station may have to work with all comers.

One can easily see that apparatus which might be eminently suitable in one case would be very unsuitable in the other. Stations in the first category can use uncommon wave-lengths and thus free themselves, to a large extent, from interference from other stations, besides being able to use a large amount of power without causing interference. The Marconi trans-Atlantic stations in Ireland and Nova Scotia use a wave-length of over 6,000 metres (50,000 ~ per second) and are thus free from disturbance from ships which generally use 300 to 600 metres.

Stations of the third class, on the other hand, should be able to call, or be called up by, ships or land stations, fitted with any make of apparatus covering a wide range of frequency.

To appreciate the difficulties due to interferences one has only to consider a station on the Kentish coast, with half-a-dozen ships within range all wishing to communicate with the coast station. They can only communicate one at a time, and each operator naturally tries to "catch the speaker's eye," which in this case is the coast operator's ear, by calling often and loudly, notwithstanding any regulations to the contrary. The same thing may be going on at other coast stations on both sides of the Channel. In addition to this we have English and French warships and dockyards working at the same time. If every station or every ship had a different wave-length it might be possible to tune the others out to a certain extent, but for the sake of uniformity and convenience in working, the majority of stations have about the same wave-length, so that when one is tuned to the desired station, one is also tuned to the disturbing stations. The result is that one station tries to shout the other down and the successful working of all the stations is greatly hindered. At the City and Guilds College in South Kensington one of the aerials is a single wire 260 ft. high and with this one can sometimes hear half-a-dozen stations sending simultaneously at approximately the same wave-length, making it absolutely impossible to read any one of them.

Apart from all this, there are the atmospheric disturbances, which vary very much from time to time. One station receiving from another a thousand miles away will certainly hear every lightning flash over a large part of the earth's surface. These atmospheric disturbances are often strong enough to make working impossible over any but very short distances, even when the weather conditions locally look ideal.

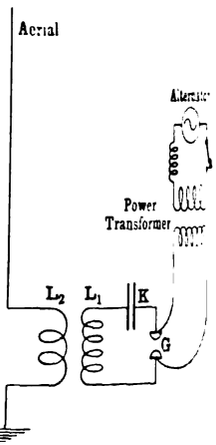

Fig. 1.

Whether one can receive or not in spite of these atmospheric disturbances depends on the loudness and nature of the signals, so that one can become more and more independent of the atmospheric conditions by increasing the power employed and by making the signals easily distinguishable from the sounds caused by the disturbances.

Recent developments in the sending apparatus have been largely directed towards obtaining freedom from interference. This has been sought in two ways: Firstly, by sending out well-sustained trains of waves of one definite frequency, giving sharper tuning, and secondly, by giving the signals a high musical pitch, easily distinguished from the crackling noises caused by atmospheric disturbances and also from other stations having notes of a different pitch. The spark-gap must be so designed that these characteristics are retained when very large powers are employed. A spark-gap may work excellently when the power is small, but fail entirely when the power is increased. Absolute reliability and constancy are of far greater importance than efficiency, although any improvement in the latter is to be welcomed, not so much for the saving of power as for the reduction in size and cost of the apparatus.

Fig. 1 may be taken to represent diagrammatically the sending apparatus of almost every system, by whatever name it may be called. In all except the smallest installations, the sparking coil with hammer or mercury break has been replaced by an ordinary power transformer supplied with alternating current, as shown in the figure. The coils L_1, L_2 constitute an air-core Tesla transformer of few turns. It is sometimes connected as an auto-transformer, *i.e.*, with a single winding tapped off at different points, but this alters nothing so far as the principle is concerned. If coil L_2 is far removed from coil L_1, each discharge of the condenser K across the gap G will cause a damped oscillation in the primary circuit GKL_1, as shown in Fig. 2. The rapid damping is mainly due to the dissipation of energy in the spark-gap. The time, T, of a complete oscillation depends only on K and L_1 and is usually about 1/500,000 second, corresponding to a wave-length in space of 600 metres. All the energy stored in the condenser at the moment of breakdown is dissipated as heat in the gap and in the remainder of the oscillatory circuit. It is seen that the oscillatory disturbance caused by one spark lasts about 1/50,000 second. Nothing further happens until the condenser is charged up

* Paper read before Section G of the British Association at Portsmouth.

Digitized by Google

to the same potential difference as before. If the gap is made so long that the spark can only just jump it, the next spark may not occur until several half-cycles of the alternating supply have passed, the voltage across the secondary of the power transformer gradually building up due to resonance. This resonance is obtained by adjusting the speed of the alternating-current generator. The result will be that, with an alternating-current supply of 50 cycles per second, the sparks may occur at intervals of 1/20 to 1/30 second (Fig. 2). This is the method which was largely used two or three years ago and which is still used by the Eiffel Tower and many other stations.

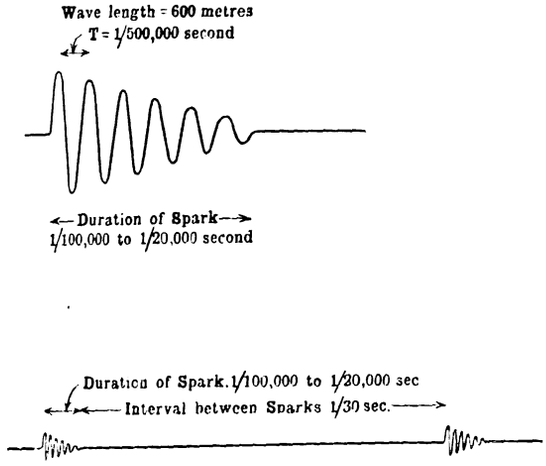

FIG. 2.—SENDING WITH 30 SPARKS PER SECOND.
The duration of a Morse dot is about one-twentieth of a second.

If the coil L_2, which with the aerial constitutes an oscillatory circuit of the same frequency as the circuit GKL_1, is loosely coupled with the coil L_1 so that about 5 per cent. of the magnetic flux of L_1 links L_2, a part of the oscillating energy will be transferred to the aerial and there partly radiated out into space and partly dissipated in the aerial, coil, and earth connection. The oscillogram (Fig. 3) shows the nature of the primary and aerial currents accompanying each spark. Owing to the loose coupling between L_1 and L_2 the transference of energy is very slow and the major portion is still dissipated in the spark-gap. From experiments made at the City and Guilds College it has been found that under the most favourable circumstances 30 per cent. of the primary energy can be transferred to the aerial. If the transfer of primary energy to the aerial is hastened by increasing the mutual inductance between L_1 and L_2, the energy surges backwards and forwards between the two circuits and gives us the phenomenon of beats. The oscillograms (Figs. 4 and 5) show the nature of the primary and aerial currents as the coupling is increased. Instead of a wave of one definite length, say 600 metres, a pulsating oscillation is sent out, which may be looked upon as made up of two ordinary damped waves with lengths of, say, 500 and 700 metres. This will be received almost equally well on the receiving aerial whether it be tuned to 400, 600 or 800 metres or any other intermediate wave-length.

In Figs. 9 and 10 are plotted the currents in the receiving apparatus as its natural frequency is varied. The two figures refer to different installations; in each case a series of curves is given for different degrees of coupling between the coils L_1 and L_2. With the ordinary spark-gap it is obviously impossible to increase the coupling much above 7 or 8 per cent. without sacrificing sharpness of tuning and thus causing undue interference with stations working at other wave-lengths. Apart from the question of interference, there is little increase of efficiency to be obtained by increasing the coupling beyond this value.

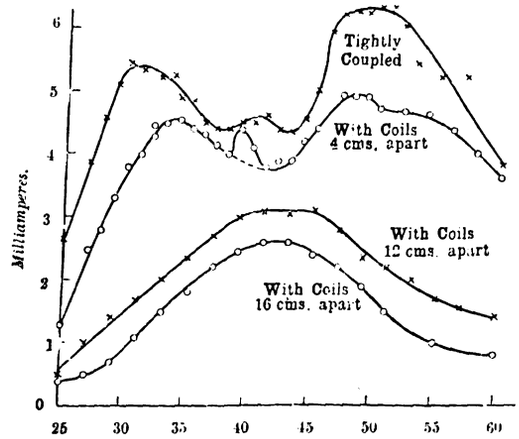

FIG 9.—SENDING ON FIVE-WIRE AERIAL, USING SMALL SPARK COIL AND PLAIN GAP WITHOUT AIR BLAST.

These are the conditions under which the majority of stations are working at the present time, but during the last three or four years a great amount of research work has been done with the object of improving these conditions.

In Fig. 10 it will be noticed that when the coupling is tight, the aerial oscillation contains waves of three different frequencies, one high and one low, corresponding to the constituents of the beats, and one of the natural frequency of the aerial alone. This shows that during a part of the time the aerial oscillated freely, uncoupled from the primary circuit. The reason for this can be seen from the oscillogram, Fig. 6. In the experiment to which Fig. 10 refers, the spark-gap was exposed to an air-blast, so that whenever the amplitude of the current in the primary oscillating circuit was small, there was a tendency for the air-blast to remove the column of hot air and metallic vapour and thus to extinguish the spark. This will obviously occur at a moment when all the energy is oscillating in the aerial and will prevent it surging back into the primary circuit. The aerial will now continue to oscillate at its natural frequency until the energy is all radiated or dissipated. In Fig. 10 not only was there an air-blast

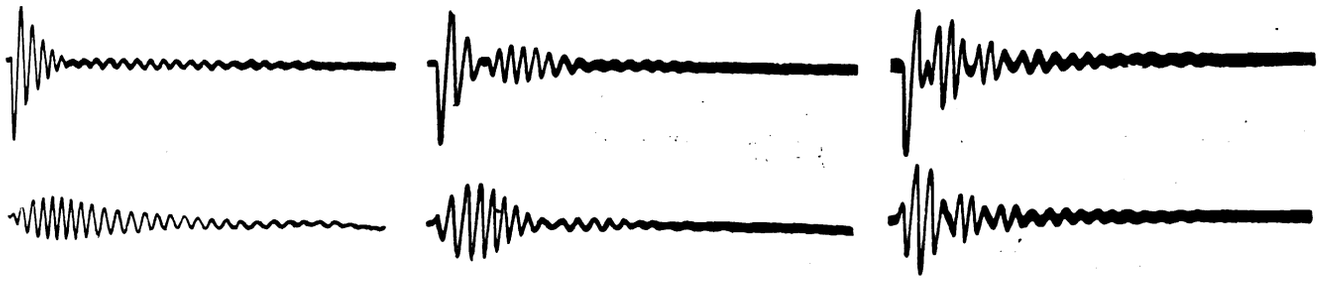

FIG. 3. FIG. 4. FIG. 5.

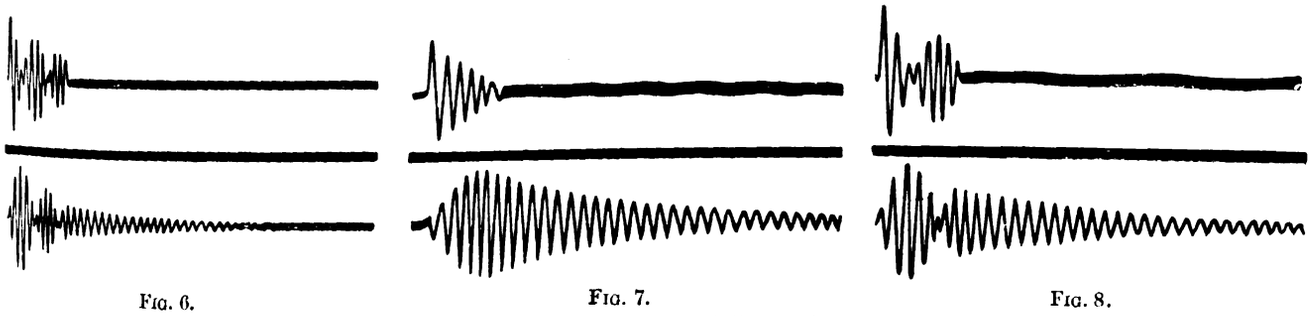

FIG. 6. FIG. 7. FIG. 8.

In all the Oscillograms the Upper Curve refers to the Current in the Primary Oscillating Circuit and the Lower Curve to that in the Aerial.

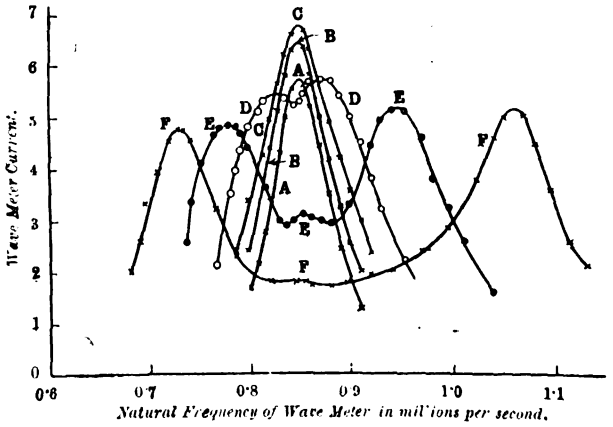
Digitized by Google

but the electrodes were comparatively large and the spark-gap short, so that no part of the spark was far removed from the large mass of cold metal tending to condense the metallic vapour and thus lower the conductivity of the spark.

This quenching of the spark was discovered in 1906 by Prof. Max Wien and was afterwards taken up by the Telefunken Company, who have evolved a form of spark-gap in which the quenching is very effective. With this gap the primary and aerial currents will be as shown in the oscillogram, Fig. 7. The gap acts as a very quick-acting minimum-current cut-out, and opens the primary oscillating circuit at the first opportunity, viz., when all the energy has been transferred to the aerial. The time during which the two circuits are coupled is very short, the energy wasted in the spark-gap is reduced, and the major portion of the energy oscillates freely in the aerial and is radiated as a damped train of waves at its natural frequency. In this way it is claimed that 75 per cent. of the output of the alternator is transferred to the aerial.

It is obviously advantageous to shorten the duration of the spark as much as possible by tightening the coupling between the coils L_1 and L_2, and thus hastening the transfer of energy to the aerial. If this be overdone, however, the gap will fail to quench at the first minimum and we may get the conditions shown in Fig. 8, or even Fig. 6, with a great loss both in efficiency and sharpness of tuning.

Wien first obtained quenching by the use of very short spark-gaps, and this is the method which the Telefunken Company has adopted, although other methods have since been discovered. The spark is made to occur between the parallel faces of discs of copper or silver placed about 1/100 in. apart, the discs being separated by thin annular rings of mica which also serve to shut the sparking spaces off from the air. The number of these discs in series depends on the voltage and power required. This form of gap is undoubtedly complicated and expensive, not only in first cost but also in subsequent up-keep.



Using 10 in. spark coil with mercury break. Length of spark gap 1·2 mm. with air-blast.
Primary capacity, 0·00567 microfarad. Secondary capacity, 0·00198 microfarad.
Resistance in secondary, 6·36 ohms.

A coupling = 2·9 per cent.	C coupling = 7·8 per cent.	E coupling = 21·4 per cent.
B " = 4·75 "	D " = 12·55 "	F " = 36·3 "

FIG 10.

Those who have picked up the time signals and weather reports sent out daily from Norddeich near Bremerhaven will have noticed that although the signals are very clear and easily distinguished from extraneous sounds, they often decrease in loudness after working for some time, and have been known to fail altogether for a few seconds in spite of the efforts of the operator. This may have been due, of course, to some exceptional cause not connected with the gap, but it is almost what one would expect when using such minute gaps as 1/100 of an inch. It seems therefore, at present, that the increased efficiency due to the quenched spark is obtained by the sacrifice, to a certain extent, of reliability and simplicity.

Turning now to the receiving apparatus, we find that the filings coherer has practically disappeared. The reception of the signals is now always aural. The detectors now employed in conjunction with a telephone receiver are not only much more sensitive than the filings coherer operating a Morse inker, but enable the operator to discriminate between the signals being sent to him and the various disturbances picked up by the aerial, which, as we have already seen, is a matter of ever-increasing importance.

The magnetic detector used by the Marconi Company is ideal in its simplicity and reliability, but is not so sensitive as the electrolytic or the mineral contact detector. The Telefunken Company have recently given up the electrolytic detector in favour of a detector of the latter type. Another type of detector used to a certain extent is the Fleming valve, which combines extreme sensitiveness with comparative simplicity and reliability.

Although there are many ways of arranging the receiver connections, Fig. 11 may be taken as typical of the usual arrangements when using a mineral contact detector. The high-frequency oscillation picked up by the aerial is transferred by means of the oscillation transformer L_3 L_4 to the tuned oscillatory circuit KL_4. Shunted across the condenser is the detector—consisting simply of a piece of zincite in contact with a piece of pyrites—together with the telephone receiver of several thousand ohms resistance. The telephone is shunted with a condenser, which must have such a capacity that it acts as a conductor to the high-frequency oscillations enabling them to pass through the detector without passing through the highly inductive telephone receiver, but as an insulator to currents of telephonic frequency, thus forcing them to pass through the telephone.

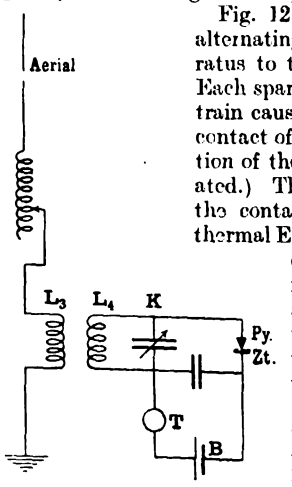


FIG. 11.

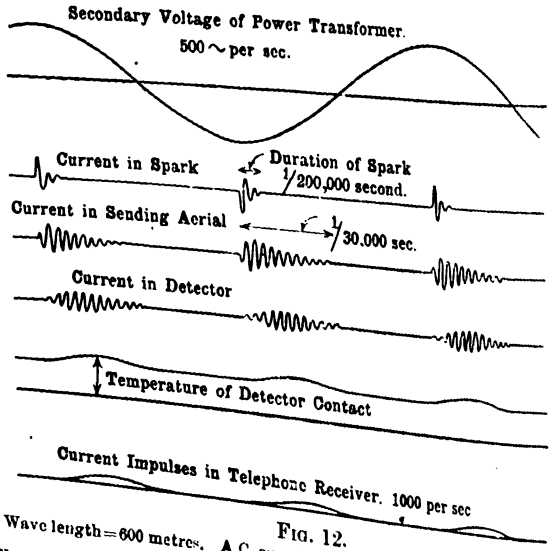
Fig. 12 explains the various stages from the alternating-current supply of the sending apparatus to the currents in the telephone receiver. Each spark causes a wave-train, and each wave-train causes a momentary heating of the point of contact of the detector. (In the figure the duration of the wave-train has been greatly exaggerated.) This will cause a momentary variation in the contact resistance and will also produce a thermal E.M.F., with the result that a momentary current passes through the telephone or, if, as is sometimes found advantageous, a steady current is maintained through the telephone by means of the cell B, this steady current will suffer a momentary variation.

Thus each spark gives an impulse to the telephone diaphragm and the pitch and nature of the note heard in the telephone receiver will depend entirely on the frequency and regularity of the sparks. It is here that one of the greatest improvements has taken place. Until recently the sparks followed one another so slowly or so irregularly that the sound heard in the telephone could not be called a note but was merely a crackling noise. A great number of stations are still working in this way, and the signals they send out are very difficult to distinguish from atmospheric disturbances and other extraneous noises. It is now realised, however, that by giving the signals a pure musical note of high pitch, they can be readily heard and distinguished above comparatively loud atmospheric disturbances and in spite of interference from other stations, unless these stations happen to be working with a note of the same pitch.

Another very important point in this connection is the great increase in the sensitiveness of the telephone receiver as the pitch of the note is increased.



Wave length = 600 metres. A.C. supply from 500 ~ alternator. Quenched spark.

FIG. 12.

To produce a musical note of high pitch it is necessary to make the sparks follow one another rapidly and with great regularity. When sending at a speed of 20 words per minute, the duration of a dot will be about 1/20 of a second, so that with a spark frequency of 30 per second the dot will consist of one, or at the most, two sparks, whereas with a spark frequency of 1,000 per second, the dot will consist of 50 sparks. The former was quite enough to actuate a filings coherer, but would merely cause a blow on the telephone diaphragm, whereas the latter would give a short piping note in the receiver.

By increasing the alternating supply voltage or by shortening the spark-gap, a large number of sparks can be made to occur during each

Digitized by Google

half-cycle, but they will occur too irregularly to produce a musical note unless steps are taken to make the sparks occur at regular intervals. This can be done by replacing the stationary gap by two discs revolving at high speed, the rims of the discs being provided with projecting knobs between which the sparks jump.

The simplest way of obtaining 1,000 sparks per second with great regularity is to use an alternator giving 500 cycles per second and to adjust the voltage until the gap breaks down once every half-cycle as shown in Fig. 12. To ensure regularity the gap must be kept cool and the after-effects of each spark quickly removed. With the ordinary stationary gap this can be done by means of an air-blast, but with the Marconi revolving discs the air-blast will hardly be necessary. In the new Telefunken gap the quenching action, which we have already considered, has to extinguish the spark 1/200,000 second after it has jumped, so that after 1/1,000 second the gap should have lost all traces of the spark. The quenching action has thus to play a double part, the first affecting the nature of each spark and the resultant oscillation, and the second affecting the regular succession of sparks.

One of the most recent developments, although hardly yet beyond the experimental stage, is the introduction of the telephone relay. By placing one of the telephone relays, recently invented by Mr. S. G. Brown, between the detector and the telephone receiver, signals which are otherwise quite inaudible can be easily read. The Telefunken Company has recently experimented with an apparatus somewhat similar in principle and known as a tone augmenter.

The distances over which communication can be maintained with a given supply of power depends on the height and size of the aerial, on the nature of the intervening country and on the type of detector employed.

A safe guarantee under very unfavourable conditions is about 50 miles per kilowatt of alternator output but with favourable conditions and sensitive apparatus, distances of over 500 miles per kilowatt have been covered.

Practically all the radio-telegraphic apparatus working commercially or being installed at the present time is based on the principles which we have considered. With the exception of the spark-gap and the detector employed, the differences are non-essential. No mention has been made of the generation of undamped waves by means of arcs, as this system has not yet made the revolutionary changes in radio-telegraphy which many anticipated.

A NEW TREATMENT FOR PREVENTING SCALE IN BOILERS.*

BY T. R. DUGGAN.

It is not quite known why, in the generation of steam, certain salts of calcium and magnesium form hard crusts or scale. All engineers try to minimise this evil, knowing that $\frac{1}{8}$ in. thickness of scale means a loss of about 20 per cent., $\frac{1}{4}$ in. equals a loss of 40 per cent., and $\frac{3}{8}$ in. of scale a loss of about 50 per cent. of heat.

After many trials, Brandes has discovered an apparatus—"The Luminator"—which so changes water allowed to flow over it that when used in steam boilers little scale is deposited, old scale is softened and detached from the plates, and the precipitable salts are deposited as powder. I should hesitate to offer this for serious consideration were there not men of repute and integrity who have proved it in practice, as well as several plants working successfully in this country.

The treatment consists in allowing water to run down an aluminium plate of special dimensions, with corrugations of a particular size, according to the character of the water to be treated. It is only necessary to brush the channels well to keep them clean.

Storage tanks and mains, if far from the boiler, must be coated with a non-conducting composition—any bituminous varnish will do—and the water must reach the boiler as soon after treatment as possible. In any case, to get the maximum effect, the water must be used within seven days of its treatment.

The theory of the action of the "Luminator" is that, by the passage of water over the metal channels at certain speeds a current of electricity is induced, the water being negative and plates positive, and a kind of ionisation of the salts takes place, which makes them fall out in an amorphous form; at the same time aluminium is by friction and electrical action abraded from the surface as colloidal aluminium, which after a time is changed in the water. The best results are obtained when the "Luminator" is facing either north or south and exposed to direct light; in the dark the apparatus almost ceases to work.

The action within a steam generator is somewhat obscure, but in all probability the colloidal aluminium acts as a series of nuclei or active centres for the evolution of carbon dioxide and the crystallisation of salts, while the aluminium particles also combine with the dissolved oxygen of the water, and so deoxidise it. As corrosion of boiler plates is supposed to be caused by the presence of free oxygen in the water, this action should diminish the corrosion of boilers; such is found in practice to be the case. For instance, a boiler which was usually red with ferric oxide at the steam and water line, a belt of about 12 in. wide became purple black like new plates after using water treated by this process. This action is not confined to the steam and water junction, but goes on all over the boiler until it becomes coated with a smooth adherent semi-metallic coating of magnetic oxide of iron, which seems to prevent centres of crystallisation upon the plates and precipitates the salts as a powder.

* Abstract, from the "Journal" of the Society of Chemical Industry, of Paper read at the Chemists' Club, New York.

DISCUSSION.

Mr. W. A. CONVERSE said that it seemed to be generally agreed that the change effected by the "Luminator" was physical and not chemical. The water, before and after treatment, showed no difference upon analysis, but, upon boiling, was said to show considerable difference in precipitation. He had himself examined samples before and after treatment and could not find any difference.

Mr. F. B. HERRESHOF said that an experiment was tried with a feed water heater made in Boston some 15 or 20 years ago. It had a coil with a large surface exposed, so that the temperature of the feed was brought up to nearly 300°F. It was assumed that sulphate of lime would separate out at about 300°F., and it was claimed by the makers that all the carbonate would separate out. There were about 5 grains to the gallon of carbonate, as well as sulphate, and analysis showed that none of the carbonate was separated. Thus, at even that high temperature, the presence of carbonic acid which could not get away kept the calcium carbonate in solution; but calcium sulphate, if present in large enough amount, separated out. In a steam boiler the conditions were different, because the steam evolved swept away the carbonic acid as fast as it was disengaged from the bicarbonate; and the insoluble carbonate of lime, probably at first a fine powder, began to crystallise and form scale on parts of the boiler. Calcium sulphate was soluble in 400 parts of cold water; but at high temperatures, such as 300 F., it probably became dehydrated to a certain extent—at any rate it deposited on the tubes and parts of the boiler that became heated. The flues and crowns of boilers were hotter than the water, and it was there that calcium sulphate became attached as a very hard scale. How was this electric influence on a small scale to prevent calcium bicarbonate from decomposing at that temperature; or the carbonic acid from being swept out by the steam? How could it prevent calcium sulphate from decomposing when heated to a high temperature and forming scale?

Mr. JEROME ALEXANDER said that the fact that metals dissolved in water in the colloidal condition had long been known. In this particular case, aluminium and its compounds, whatever they might be, acted substantially as protective colloids. The various reactions described by Mr. Herreshof actually did occur; but in the presence of the aluminium or alumina compounds, the insoluble products separated as colloids and remained in suspension so that they passed out of the boiler when the boiler was blown off. He had never heard of a metal acting as a protective colloid, and he doubted if the metal aluminium could so act. Possibly aluminium oxide might, and so prevent precipitation. There appeared to be no doubt as to the facts stated by Mr. Duggan, and therefore one could only search for the most reasonable explanation of them. It looked as if the aluminium compounds, of whatever nature they might be, did act as protective colloidal substances.

Dr. FERRIS said that it was a common practice in the west to put zinc slugs in boilers, particularly tubular ones, where the heat was principally in the flues, to prevent the formation of scale. The precipitate remained in powder form and could be blown out very easily. But the zinc slugs in time dissolved. In an 80 H.P. boiler two or three zinc slugs of 25 lb. each would disappear in a month.

Mr. T. R. DUGGAN, in reply, said that a litre of water was run through the "Luminator" apparatus 10 times, and another litre of the same water was run over an enamelled plate the same number of times. Both samples were then heated to 80°C. for 10 or 15 minutes. The experiment showed a loss of 20 per cent. of temporary hardness in the water run through the "Luminator," while the other lost about 3 per cent. Aeration had nothing to do with it. There was no limit to the hardness which could be treated in the apparatus, but for such hard waters as reached, say, 80 grains per gallon on Clark's scale, an apparatus some 20 ft. long would be needed. The loss in weight of the aluminium was impossible to measure, it was so infinitesimal. A boiler using the "Luminator" should be blown off frequently, more especially in the first stages of its use, because old scale came off so rapidly that it accumulated at the bottom, and if permitted to remain there might result in burning the boiler. It was extraordinary what an effect the treatment had upon foaming. In every case where these machines had been used, foaming practically ceased. Waters containing ferrous sulphate could be treated, but ferrous carbonate would deposit on the aluminium plates, so they had to be continually cleaned, making it almost impossible to treat such waters. Milk, when passed through the apparatus, was found to keep an extraordinarily long time; whereas the same milk, not passed through it coagulated and became sour quickly. The corrugations had no function except to increase the surface of the plate. Zinc slugs were used in Great Britain many years ago, in marine boilers particularly, but for some unknown reason had been abandoned within the last 10 years.

The Rates for Subscription to "THE ELECTRICIAN" are as under:—

	Year.	Half-Year.	Quarter.	
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.	Post free, payable in advance.
Canada	28s. 3d.	14s. 6d.	7s. 6d.	
Postal Union	30s. 0d.	16s. 0d.	8s. 0d.	

New volumes of "THE ELECTRICIAN" commence in April and October.

(This charge includes all the numerous Supplements.)

Vols. I to LXVI. can now be supplied. Price on application.

"THE ELECTRICIAN" SERIES OF STANDARD ELECTRICAL BOOKS

can be obtained of all Booksellers at Home, in the Colonies, and Abroad.

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. Published annually in February, corrected to mid-February. Established 1882. A very valuable advertising medium, covering the entire Industry. SUBSCRIPTION Price (which is received *in advance* up to Jan. 31st in each year for the next following edition) 8s. 6d. nett, postage 9d. extra. Published price 15s. nett, postage 9d. extra. Postage to British Colonies, 2s; Europe, 2s; U.S.A., 3s. 6d.; other countries, 2s. 6d. *Digest of Contents of the 1911 Edition sent free on application.*

THE PRACTICAL WIRELESS SLIDE RULE. By Dr. H. R. Belcher-Hickman. Price 2s. 6d. nett. *Reduction on quantity.*

LIVINGSTONE'S DIAGRAM FOR THE EASY CALCULATION OF SHAFT AND BEAM DEFLECTIONS. By R. Livingstone. 2s. 6d. nett. By post in tube, 2s. 10d.

"THE ELECTRICIAN" PRIMERS (61 Primers in all, and a GLOSSARY). Single Primers 3d. each post free. *New and Enlarged Edition in One Complete Vol. or Three Separate Vols.* FULL PROSPECTUS FREE.

ELECTRIC TRACTION ON RAILWAYS. By Philip Dawson. Price 25s. nett. *Prospectus free.*

ALTERNATING-CURRENT MOTORS. By Dr. Rudolf Goldschmidt. Price 6s. 6d.

THE SHOT-FIRER'S GUIDE: A Practical Manual on Blasting and the Prevention of Blasting Accidents in Mines, Quarries, &c. By W. Maurice. Price 3s. 6d. nett.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. Wilkinson, M.I.E.E. *New Edition.* Now ready. Price 15s. nett.

ELECTRIC BLASTING APPARATUS AND EXPLOSIVES: With Special Reference to Colliery Practice. By W. Maurice. Price 8s. 6d. nett.

THE ELECTRIC FURNACE IN IRON AND STEEL PRODUCTION. By John B. C. Kershaw, F.I.C. Price 3s. 6d. nett.

BRAKES FOR TRAMWAY CARS. By H. M. Sayers. Price 3s. 6d. nett.

THE MECHANICAL DESIGN AND CONSTRUCTION OF COMMUTATORS. By R. Livingstone. Price 6s. nett.

THE ALTERNATE-CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. [abroad 13s.

VOL. I.—Price 12s. 6d. post free, abroad 13s. VOL. II.—Price 12s. 6d. post free,

HANDBOOK OF THE ELECTRICAL LABORATORY AND TESTING ROOM. Very fully illustrated. By Dr. J. A Fleming. Vol. I., 12s. 6d. nett, Vol. II., 14s. nett.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. Fleming. 6s. nett.

ELECTRICAL LABORATORY NOTES AND FORMS. Arranged by Dr. J. A. Fleming, M.A., F.R.S. Single copies 4d. nett, or in dozens at 3s. 6d. nett. Complete Sets of 50 Notes and Forms, 12s. 6d. nett, or in strong portfolio, 14s. nett; or bound in strong cloth, 15s. nett. Spare Copies of Tabular Sheets, 1s. per dozen. Portfolios, 1s. 6d. each. Sectional paper, 1s. per dozen sheets. *Complete Prospectus post free on request.*

ELECTRICITY METERS: THEIR CONSTRUCTION AND MANAGEMENT. By C. H. W. Gerhardi. Profusely illustrated. Price 9s. nett.

ELECTRICITY IN HORTICULTURE. By Prof. S. Lemstrom. Illustrated. 3s. 6d nett.

RADIO-ACTIVITY: AN ELEMENTARY TREATISE, FROM THE STANDPOINT OF THE DISINTEGRATION THEORY. By Fredk. Soddy, M.A. Fully illustrated. Price 6s. 6d. nett.

ELECTROMAGNETIC THEORY. By Oliver Heaviside. Vol. I. Price 12s. 6d. Vol. II. Price 12s. 6d. *Vol. III. in the press.*

MOTIVE POWER AND GEARING FOR ELECTRICAL MACHINERY. By E. Tremlett Carter, C.E., M.I.E.E. Revised by G. Thomas-Davies, A.M.I.E.E., F.C.S. Price 12s. 6d. nett.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. Ewing, B.Sc., F.R.S., F.R.S.E. Price 10s. 6d.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. Kennelly and H. D. Wilkinson, M.I.E.E. Price 6s. 6d.

ELECTRIC MOTIVE POWER. By Albion T. Snell. Price 10s. 6d. nett.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. Gelpel and H. M. Kilgour. Price 7s. 6d. nett.

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. Elton Young. Price 10s. 6d.

STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By H. K. C. Fisher and J. C. H. Darby. Price 7s. 6d. nett.

SIGNALLING ACROSS SPACE WITHOUT WIRES: THE WORK OF HERTZ AND HIS SUCCESSORS. With new Chapter on Tuning. By Dr. Sir Oliver J. Lodge. Price 5s. nett.

THE ART OF ELECTROLYTIC SEPARATION OF METALS. By Dr. G. Gore, LL.D., F.R.S. [Price 10s. 6d.

ELECTRO-CHEMISTRY. By Dr. George Gore. Price 2s.

BEGINNER'S MANUAL OF SUBMARINE CABLE TESTING AND WORKING. By G. M. Baines. Price 7s. 6d. nett.

CARBON MAKING FOR ALL ELECTRICAL PURPOSES. By Francis Jehl. Price 10s. 6d.

"THE ELECTRICIAN" WIREMAN'S POCKET BOOK. Price 5s. nett.

"THE ELECTRICIAN" HANDY WIRE TABLES FOR THE POCKET. By P. B. Down, Wh.Ex., A.M.I.Mech.E. Price 2s. 6d. nett.

THE RATING OF ELECTRIC LIGHTING, ELECTRIC TRAMWAY, AND SIMILAR UNDERTAKINGS. By W. G. Bond, M.I.E.E. Price 2s. 6d. nett.

DRUM ARMATURE WINDING AND COMMUTATORS. By F. M. Weymouth. 7s. 6d.

PRIMARY BATTERIES: THEIR CONSTRUCTION AND MANUFACTURE. By W. R. Cooper. Price 10s. 6d. nett.

"THE ELECTRICIAN" INDUSTRIAL SUPPLEMENT.

With "THE ELECTRICIAN" for Sept. 14, 1906, was issued the first of a series of "Industrial Supplements," to be published from time to time with "THE ELECTRICIAN." The fifty-third issue of the Supplement published (Gratis) with the number of "THE ELECTRICIAN" for September 23, 1910, was the last of the monthly issues. "THE COMMERCIAL AND INDUSTRIAL SUPPLEMENT" to "THE ELECTRICIAN" is now issued weekly (Gratis). It will be found towards the end of the present issue.

NOW READY.

Vol. LXVI. of "THE ELECTRICIAN." Bound in Publisher's covers. Price 17s. 6d. Postage U.K. 1s. extra, abroad 2s. 6d.

Cases for binding Vol. LXVI. are now ready, price 2s.; post free, 2s. 3d.

SIR WILLIAM RAMSAY'S ADDRESS TO THE BRITISH ASSOCIATION.

Of all the tasks that fall to the lot of a distinguished man of letters or science, that of composing a Presidential Address to the British Association is by no means the least difficult. At the best he can please only a small percentage of his hearers, for some will understand and disagree, while many will not understand and will be correspondingly discontented. Sir WILLIAM RAMSAY, on the present occasion, has committed himself to nothing very deeply, but has touched on a variety of subjects calculated to interest that section of the general public which attends the British Association. Some of his points are, however, worthy of careful consideration, and not the least of these is to be found under the head of education: we refer to the evil of the present-day examination system. Unfortunately, it must be admitted that examinations of some kind are a necessity; there is at present nothing that could fill the gap which would remain if examinations were abolished. Bad as the system is, however, it is, nevertheless, susceptible of easy improvement. The trouble is that examiners, and even teachers, attach too much importance to examinations, and very often the tests themselves are conducted by the wrong persons. Perhaps the most glaring example of how not to do it is found in what is called the "external examination." A syllabus is laid down by an examining body, and students are carefully crammed in the subject-matter therein for several months on end. At the conclusion of this period there is a final furbishing up with a text book at the very threshold of the examination room; then a paper of per-

Digitized by Google

haps ten questions, set with a view to ascertaining not how much a student has digested, but whether he has retained certain particular points. It is no exaggeration to say that a student who has been well taught may stand less chance of success in such a test than one who has been crammed on the bare syllabus. It must be evident that a teacher, who has had a student working under him for two or three years, knows far more about his man than the most distinguished examiner can find out in a couple of hours; yet the latter is the one to decide the fate of the unfortunate student. If Sir WILLIAM RAMSAY will only take some steps towards abolishing this iniquitous system we feel sure he will not lack support. That the importance of the matter is being realised will be apparent from the discussion which took place in Section L on Friday, when it was suggested that application should be made for the appointment of a Royal Commission to consider it.

The next point of interest in the Address relates to the positions of radium and its descendants in the periodic table, in which it is suggested that allotropy may be due to gain or loss of electrons, accompanied by positive or negative heat change. Taking as his text the disintegration of radium, Sir WILLIAM proceeds to descant upon the waste of coal which goes on. He calls attention to the enormous amount of energy contained in a minute quantity of radium, and illustrates it by striking figures. Unfortunately, however, the rate of liberation is far too slow to be of practical use, and, even if some means of accelerating it were discovered, then the quantity of radium available is much too small to have any effect on the rate at which our remaining coal store is being used up. Sir WILLIAM refers to the idea of obtaining energy from the tides, from the wind and from the sun, and, although this could be done, yet the amount would be insignificant, and, what is equally important, it would not pay—at all events, at present. Hence, until the happy day comes when some new store of energy is discovered, the best thing the nation can do is to take care of the coal it has left. It is calculated that England has enough coal remaining to last her 175 years; unless, therefore, some substitute is found the prospect is not a very cheerful one, for the nation can no more live without coal than a man can live without food. The right note is struck when Sir WILLIAM RAMSAY advocates the adoption of economical methods in the use of coal. Since the store must be exhausted, let it be exhausted as slowly as possible; if a method can be found of doing as much with a ton of coal as was formerly done with a ton and a quarter, let that method be adopted without delay. As a matter of fact, this is exactly what has been going on for a great many years, and the "*laissez-faire* plan of leaving to self-interested competition the combating of waste" is not so "*laissez-faire*" as the President might think. Strenuous endeavours are being made by engineers all over the country to reduce coal consumption, not perhaps from a purely altruistic motive, but because it pays. His suggestion that electricity should be generated at the pit's mouth and distributed at high pressure is a somewhat belated one; it has already been done, and in all probability the method will be extended as time goes on. It must be recognised, however, that a point is soon reached when this plan no longer becomes commercially possible. Presumably, this is the point at which Sir WILLIAM suggests State aid in the form of "loans at an easy rate of interest." We fear it will be a long time before any Chancellor of the Exchequer is bold enough to attempt the inclusion in his Finance Bill of a clause to transfer a portion of the national revenue to an electricity supply undertaking with the object of securing coal to posterity. It is a magnificent idea, but we fear it is a long, long way off realisation.

Sad as it may be, it seems that the saving of coal must, for very many years, be left to the efforts of engineers, who will use their wits, not in the interests of humanity, but with a view to diminishing that magical item "coal costs." Of course, if the State took over the electric supply industry, the matter would be on an entirely different footing; but we imagine that this also is not likely to take place in the immediate future.

Sir WILLIAM RAMSAY has done the country a real service in re-calling attention to this subject, and we can only hope that his Address will be read with the attention it deserves. At all events, his warning is a timely one, and he has discharged his duty by stating the case in such a way that there can be no mistake about it.

REVIEWS.

(Copies of the undermentioned works can be had from THE ELECTRICIAN Office, post free, on receipt of published price, adding 3d. for books published under 2s. Add 10 per cent. for abroad or for foreign books.)

The Elements of Telephony. By ARTHUR CROTCH. (London, 1910: E. & F. N. Spon.) Pp. 90. 1s. 6d. net.

Within the limits of a modest volume of 90 pages the author has outlined the main features of a present-day telephone system in a way which should enable a reader who has some little knowledge to start with to obtain a clear and intelligent understanding of the inner workings of a modern exchange.

The general arrangement of the book is excellent. After a discussion of first principles in the introductory chapter, the reader is led by easy stages from the simple magnetic telephone of Bell up to the intricacies of the large common battery exchange. The text is plentifully illustrated by circuit diagrams and photographs of apparatus. The former, although of necessity rather small, are nevertheless very clear and show evidence of considerable care having been taken in their selection and preparation.

In a book of this kind one does not look for detailed descriptions of the thousand-and-one types of apparatus now in use, but rather for an explanation of the salient features of a few of the more important ones, with a view to bringing out the underlying principles upon which their action depends and the conditions they are designed to meet. In this respect the author is particularly successful and his book can be recommended as eminently suitable to place in the hands of the elementary student to form a foundation for the more detailed knowledge he will afterwards acquire. H. S. T.

William Thomson, Lord Kelvin—His Way of Teaching Natural Philosophy. By D. WILSON. (Glasgow, 1910: J. Smith & Son.) Pp. 56. 2s. nett, cloth; 1s. nett, paper.

In this book the author gives his recollections of certain scenes in the natural philosophy class at Glasgow University in the early eighties, and his own personal ideas about Lord Kelvin's method of teaching. The images presented seem to us very distorted, the author and his friends forming a very conspicuous group in the centre. They seem to have belonged

Digitized by Google

to that class of student which is always on the look-out to "show off," not infrequently with disastrous results. The first chapter, on the "metric system," purports to portray a scene in the class-room and illustrates the difficulties of teaching "raw material" in bulk. In the next chapter several happy prophecies made by Kelvin in 1884 are given. They illustrate how clearly he saw the lines on which progress in electric lighting and traction would be made. The author does not throw much light as to what Kelvin meant by the "vital principle," but he airs his knowledge of Oriental religions, and thinks that Kelvin must have been actuated by the *Golden Rules*.

In the last chapter the author describes how, in a degree examination on natural philosophy, he answered the last question in a way which, although correct, was more fitted for the pages of "Punch" than for examiners' reading. The examiners being Scotch, and consequently being able to appreciate a joke without loss of dignity, decided that justice would be satisfied if the culprit had a personal interview with Sir William. The interview shows Sir William in a very pleasant light, but we are doubtful, notwithstanding the statement to the contrary, whether he really succeeded in making the author see the principle of the conservation of energy. "Conservation of energy was seen to be a verbal symbol of one aspect of what Carlyle called the 'fact of facts,' the living universe, whose 'energy' includes, as an insignificant item, the whole human race from the beginning of time, and can no more be measured by us than the ocean can be bottled in our laboratories." Personally, the reviewer thought that the conservation of energy was something quite different, but still, if philosophers are willing to accept it in the form set forth by Mr. Wilson it seems a pity to try and upset their faith.

Elektrische Winke für Architekten und Hausbesitzer By Dr. L. Block and R. Zandy. (Berlin, 1911; Julius Springer.) Pp. iv.+151. M.2.80.

Messrs. Block and Zandy have written a very interesting little work on electric installations generally which undoubtedly fulfils the title they have given it, as it certainly does contain a large number of useful wrinkles which should appeal not only to architects and householders for whom it has been mainly written but also to electric-lighting engineers in general. Of course, there are many points of difference between English and Continental installation practice which must be considered in using the book. Although, as pointed out by the authors in their introduction, the architect with a knowledge of electrical installation practice and requirements has it in his power by making from the start suitable provision for the cable runs, &c., of cheapening and facilitating the arrangement and installation of electrical wires in new buildings—of special importance in the case of buildings with ferro-concrete walls and floors—this should be done by the architect under the guidance of a responsible electrical engineer, not by the architect alone. It is impossible for the architect to gain all the necessary knowledge and experience, however well the facts are put together and condensed, in a single volume. The electrical engineer is either not consulted at all in far too many cases or is called in too late.

Chapter I. contains remarks on the installation generally—position of the connections to the supply, main runs, rising mains, distributing centres, &c. It also points out the advisability of making the necessary provision for fixing and running the wires in the case of concrete floors and gives methods of carrying this out. Chapter II. is on electric illumination. It deals with all the various types of incandescent and arc lamps in a brief but satisfactory manner. The candle-power and watt consumption are given in a very clear tabular form, especially those for arc lamps. The paragraphs on the selection of lamps, the number and candle-power, are very good, and the table for calculating the number of lamps required for different classes of rooms will also be found very instructive; it is, of course, in Hefner candle-power per square metre. The illustrations in this chapter of examples of interior illumination, both direct and indirect, are also very good. Staircase and shop-window illumination are, further, separately considered.

Chapter III. is on electric cooking and heating. Many useful data will be found in it as regards the watt consumption of various cooking utensils. Electric power in dwellings is explained in Chapter IV. It includes information and illustrations of lifts (push-button system), ventilating fans, vacuum cleaners, water pumps, small charging outfits for charging batteries for electric automobiles, electrically-driven refrigerators, &c. Chapter V. sets forth the advantages of electrically driven contractors' plant and gives excellent illustrations showing how electric power can be utilised by the contractor in building operations in numberless ways to expedite the work of excavating, removal of rubbish, &c., elevating, and so on.

The book is well and clearly written and well illustrated, and contains a number of useful hints; it reflects considerable credit upon the authors who have succeeded in setting forth the advantages of electric lighting and power in a simple and decisive manner.

STUDIES IN LIGHT PRODUCTION.*

BY R. A. HOUSTOUN, M.A., PH.D., D.SC.

(Lecturer in Physical Optics in the University of Glasgow.)

Summary.—In these studies the author deals with the theory of light production, the scope being briefly indicated by the following contents: (1) The distribution of the energy in the spectrum and the measuring of efficiency. (2) The importance of "black body" radiation and the experimental realisation of the black body. Comparison of the energy curves of a black body and of platinum, and the variation of the position of maximum energy with temperature. (3) Mechanism of flame, and the temperature, energy and efficiency of flames. (4) The Welsbach mantle and selective radiation. (5) Radiation and efficiency of the carbon glow lamp. (6) Physical properties and temperature of the arc. (7) Temperature and energy curves of the Nernst glower. (8) Efficiency of the metal filament. (9) The mercury arc and its difficulties. (10) The light of the future and the possibility of obtaining "cold light."

No. 1.—The Energy Spectrum.

It is a commonplace that our means of producing artificial light are all very inefficient. What the efficiency is in each case and the circumstances on which it depends are not generally known. The information lies scattered in a number of different periodicals. In these studies the most important facts have been collected and arranged both for the sake of reference and for information as to the lines future progress is most likely to take.

Light waves carry energy with them. Every source of light is radiating energy, and this energy is being absorbed and converted into heat by the objects on which the rays strike.

If a ray of white light fall upon a prism a spectrum is produced. Part of the energy of the original ray is reflected at the surfaces of the prism, part is absorbed in the prism and the rest is spread over the different colours of the spectrum. Suppose that the spectrum is received on a screen and we fix our attention upon that portion of it bounded by the wave-lengths λ and $\lambda+d\lambda$. The rays, the wave-lengths of which lie between λ and $\lambda+d\lambda$, bring every second a certain amount of energy to the screen; let this amount of energy be denoted by $E_\lambda d\lambda$. E_λ is a function of λ. The total energy arriving per second on the screen is $\int E_\lambda d\lambda$, the integration being carried out over the whole spectrum.

This function E_λ is very important in the theory of the efficiency of light sources, and it is necessary to consider how the variation of E_λ with λ can be determined experimentally. The brightness of the different parts of the spectrum as estimated by the eye is of no use, for the sensitiveness of the eye to different colours is by no means the same. The light energy of the different colours must be turned into heat and the quantity of heat measured. Four different instruments may be used for this purpose—the thermopile, the bolometer, the radiometer and the radiomicrometer. These instruments and the methods of working with them are fully described in

Kayser's "Spectroscopie," Vol. I., Chapters V. and VI., and in Baly's "Spectroscopy," Chapter VIII. There is also an extremely important article in the publications of the Bureau of Standards ("Instruments and Methods of Radiometry," W. W. Coblentz, Bull. Bureau of Standards, 4, p. 391, 1908) in which the relative advantages of the four methods are discussed both from the literature of the subject and as a result of tests made by the author. The radiometer has been used chiefly by E. L. Nichols and his pupils in America. It and the radiomicrometer possess the advantage that they do not require galvanometers and the disadvantage that they cannot be moved during the set of observations. Here I shall mention only a few points about the thermopile and radiomicrometer, of which instruments good types are on the market in this country. (Cambridge Scientific Instrument Co.; Keiser & Schmidt, Berlin-Charlottenburg.)

The Rubens linear thermopile is made of iron and constantan wire of diameter 0·1 mm. to 0·15 mm. It has a resistance of about 4 ohms. Constantan is an alloy consisting of 60 per cent. Cu and 40 per cent. Ni. There are 20 junctions arranged on a length of 2 cm. for receiving the light, and, of course, another 20 unexposed junctions. The junctions are soldered with beads of silver, which are flattened into discs of about 1 mm. diameter, so as to present a large surface to the rays. For mapping energy curves the thermopile is mounted in the telescope of a spectroscope, just behind the focal plane of the latter, and there are shutters in that plane for regulating the width of spectrum that is to be admitted to the thermopile. Wires lead from the thermopile to the galvanometer. When plotting an energy curve—*i.e.*, determining the function E_λ—the source of light is focussed on the slit and a screen placed before the latter. The screen is then removed and the galvanometer deflection noted. The operation is then repeated for other points in the spectrum. The galvanometer deflections do not give E_λ directly; the "slit width" correction must first of all be made. Owing to the fact that the dispersion of the prism is not normal, the range of wave-lengths falling on the thermopile at different points in the spectrum—*i.e.*, $d\lambda$—is not always the same. As the deflections are proportional to $E_\lambda d\lambda$, in order to obtain the variation of E_λ we must allow for the variation of $d\lambda$. To do this we draw the calibration curve of the spectroscope—that is, plot s, the telescope reading in angular measure in terms of λ. If we then determine $\frac{ds}{d\lambda}$ and multiply the deflections by $\frac{ds}{d\lambda}$, the result will be proportional to E_λ.

Another correction must be made before the energy curve is obtained. The absorption of light in the instrument must be corrected for. Glass absorbs all wave-lengths greater than 3μ; but if a glass prism and glass lenses be used, the deflections are influenced by the absorption of the glass from 2μ on. An energy curve cannot be plotted beyond 3μ with a glass prism and lenses, and if the region $2\mu-3\mu$ is to be determined, the absorption of the glass must be allowed for. Quartz transmits much further into the infra-red and ultra-violet than glass does; but for the infra-red region rock salt and fluorite are the most suitable materials for the prism and lenses. The absorption of the aqueous vapour and carbon dioxide in the atmosphere must be allowed for; at certain wave-lengths it influences the deflections appreciably. It is better to use mirrors in the spectroscope than lenses; all metals reflect infra-red rays well, and the focal length of a mirror being independent of the wave-length, there is no trouble in focussing the thermo-pile.

In the radiomicrometer we have both thermopile and galvanometer combined. It consists of a single loop of wire with a thermo-junction at one end suspended between the poles of a magnet by a quartz fibre. In comparison with the thermopile it has a very steady zero, but its sensitiveness is distinctly less than that of the latter when connected with a low resistance Du Bois Rubens galvanometer, which has a resistance of 10 ohms and a sensitiveness of 3×10^{-10} amperes/$\frac{1}{2}$ mm. at 1 metre distance for a period of 5 seconds. As the radiomicrometer cannot be moved, the spectroscope telescope used with it must remain fixed.

Of course, it is only the strongest sources of light, of which the energy curves can be determined directly with a thermopile or similar instrument. The light radiation from the brightest sodium flame produced by a bunsen burner would not produce a readable deflection. If the energy curve of a weak source is required, the latter must be compared with a strong source by a spectrophotometer in the visible spectrum, and by a photographic method in the ultra-violet, and the energy curve may thus be determined indirectly. There is no means of determining it in the infra-red.

The most satisfactory way of determining the wave-length in the infra-red is to calculate it from the index of refraction of the quartz or fluorite prism, or to place a very thin film of water before the slit and use its absorption bands as reference points. The positions of the latter have been accurately determined. The methods described in the text books—auxiliary gratings and interference bands—are expensive, or much more troublesome.

Suppose, now, that a number proportional to E_λ is plotted as a function of λ from end to end of the spectrum. If we wish to find what proportion of the total energy radiated is light, what we have to do is to erect ordinates at $0{\cdot}410\mu$ and $0{\cdot}760\mu$, the commonly accepted ends of the visible spectrum, and find the ratio of the area included between these ordinates to the area of the whole curve. E. L. Nichols has named this ratio the radiant efficiency of the source. At the same time he has introduced another quantity, the luminous efficiency of the light source. This is defined to be the ratio of the total energy radiated per second as light to the total energy consumed per second by the source.

Let Q = total electrical energy consumed per second, R the total energy radiated per second and L the total luminous energy radiated per second; then

$$L/Q = \text{luminous efficiency}$$

and

$$L/R = \text{radiant efficiency}$$

of the lamp.

In the case of an electric glow lamp the total energy consumed per second can be easily found from the current and the difference of potential between the terminals of the lamp. In the case of a gas flame we require to know the total quantity of gas consumed per second and the amount of chemical energy liberated by the combustion of unit mass of gas. The luminous efficiency is always less than the radiant efficiency. If the energy not radiated were zero—that is, if there were no conduction and convection losses—they would have the same value. Both quantities are extremely useful in the discussion of the performance of a light source.

A glass cell 1 cm. thick filled with water stops all wave-lengths greater than $1{\cdot}4\mu$ entirely, and absorbs the infra-red between $1{\cdot}4\mu$ and the visible spectrum considerably, but does not absorb the visible spectrum appreciably. The energy in the ultra-violet of the common light sources is very small indeed, and may be neglected in comparison with the light energy. Hence, in order to separate the light from the dark heat, it used to be the practice to pass the rays through a water filter or through a solution of alum. But a water filter transmits much dark heat as well as light, and if we attempt to determine the radiant efficiency by taking the deflections of a thermopile with and without a water filter before it the value we obtain is much too high. Some experimenters have attempted to correct for the dark heat transmitted by the water by means of solutions of iodine in carbon disulphide, which were supposed to absorb all the light and nothing but the light. The utter untrustworthiness of this correction has, however, been demonstrated by E. L. Nichols and W. W. Coblentz. ("On Methods of Measuring Radiant Efficiencies," Phys. Rev., XVII., 1903, p. 267.) Even if we use the correction the values of the radiant efficiency are still too high. Aqueous solutions of ferrous ammonium sulphate have recently been suggested as a means of separating the light from the dark heat. But it has been shown (R. A. Houstoun and J. Logie, Phys. Zs., 11, p. 672) that though they are considerably better in this respect than water filters, yet they are not good enough to afford us a satisfactory method of determining the radiant

Digitized by Google

efficiency. It should be noted that, in spite of the widespread opinion to the contrary, alum solutions do not absorb dark heat any better than water does.

Almost all the accurate determinations of radiant efficiency yet made have been carried out by a method introduced by K. Angström, which will be described later. I have recently determined ("The Efficiency of Metallic Filament Lamps," Proc. Roy. Soc., Edin., Vol. XXX., p. 555, 1910) the radiant efficiency of some metallic filament lamps by a method which, to me at least, seems preferable. The radiation was first measured in the usual way by a thermopile and galvanometer with and without a 1 cm. thick water filter, and the fraction of the total radiation transmitted through the filter determined (F). The light was then focussed on the slit of a spectroscope through the same water filter and an energy curve taken. The deflections were plotted against the scale readings and an ordinate set up at $0{\cdot}76\mu$. The area on the side of shorter wave-lengths divided by the whole area then gave the ratio (f) of light transmitted by the filter to the total radiation transmitted. It was then only necessary to find what fraction of the incident light was transmitted by the water cell. This was done with a spectrophotometer for four different points in the spectrum and the value found, 0·84, was the same for each point. The radiant efficiency was then $F/0{\cdot}84$.

The determination of luminous efficiency is much more difficult. It was the luminous efficiency that was aimed at by the old calorimetric method of measuring the efficiency of a glow lamp. The lamp was placed in a glass calorimeter and then in a similar copper one, and from the rise of temperature in the two cases, with various corrections, the ratio of the energy radiated as light to the whole energy supplied could be calculated. The heat lost by convection and conduction went to raise the temperature in both cases. But the method is in principle bad; the whole energy and the dark heat are measured and the light is obtained as the difference of two much larger quantities, both subject to considerable error of observation. Also, as has been already mentioned, water does not absorb all the dark heat, and hence some escapes from the glass calorimeter. If we wish to determine the luminous efficiency we must first of all determine the radiant efficiency; we must then find the total rate at which energy is being consumed by the source, and we must finally determine the total energy radiated per second. The neatest way of finding the energy radiated per second in any one direction is by some such instrument as Angström's pyrheliometer. To find the total energy radiated per second it is necessary to find the energy radiated in different directions and to integrate over the sphere.

So far we have considered light solely from the objective standpoint. It is now necessary to consider it in relation to the eye. The same quantity of energy in different parts of the spectrum does not produce the same intensity of sensation in the eye. The well-known curve shown in Fig. 1, taken by Sir Wm. Abney, illustrates this. The brightness of the different colours of the spectrum of the crater of the arc was compared in turn with the brightness of a white light, which could be varied by a rotating sector. The ordinates of the curve are obtained in this way, and are proportional to the brightness or luminosity of the part of the spectrum in question as seen by a normal eye. If we took an energy curve of the arc crater with the same prism and lenses, plotted it on the same diagram and divided the ordinates of the energy curve by the ordinates of the luminosity curve, the quotient would be proportional to the quantity of energy necessary to produce the same luminosity at different points in the spectrum. It varies widely throughout the spectrum, having a minimum at 510 $\mu\mu$ for low intensities, and increasing rapidly on both sides of this minimum. At 410 $\mu\mu$ it has then a value roughly 50 times the minimum value, and at 610 $\mu\mu$ one roughly 40 times the minimum value. According to P. G. Nutting ("The Luminous Equivalent of Radiation," Bull. Bureau of Standards, 5, p. 273, 1908), who refers to the reciprocal of this quotient as the visibility of the colour, the quotient for low intensities has the form $e^{\kappa(\lambda-\lambda_m)^2}$ for the normal eye, λ_m being the wave-length of the minimum measured in 10^{-5} cm., and κ being equal to 4·5.

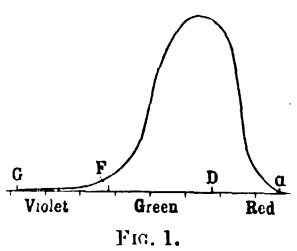

Fig. 1.

For higher intensities the maximum of visibility moves towards the yellow, and the visibility in the neighbourhood of the maximum does not vary so much with colour. At low intensities vision seems to be performed by the retinal rods alone, and at higher intensities mainly by the cones. The transition from rod to cone vision is very gradual; they are about equally in play at ordinary working intensities. It is the transition from rod to cone vision that displaces the maximum of visibility with increase of intensity.

As the brightness of the light produced depends not only on the energy of the radiation, but also on its colour, luminous efficiency, as we have defined it, has no direct connection with efficiency as ordinarily understood in connection with artificial illuminants. One source which radiates more energy between 410 $\mu\mu$ and 760 $\mu\mu$ than another may have that radiation distributed so disadvantageously over the spectrum that it gives less light than the other. C. E. Guillaume has, therefore, proposed to specify the efficiency by multiplying E_λ for every wave-length by the "visibility" for that wave-length, taking the maximum visibility in the spectrum as unity, and by dividing the quantity thus formed by the total power supplied. It may be urged against this proposal that the visibility of different colours is not very well known yet, and that in watts per candle or in candles per watt we have already a term that conveys Guillaume's meaning. Also the relative visibility of the different colours varies with their intensity. And the ordinary method of testing lamps on the photometric bench is certainly a much shorter and more accurate method for getting their watts per candle than the one suggested in Guillaume's definition. It seems to me, therefore, better to retain the old way of specifying luminous efficiency. It has, in addition, the merit of simplicity.

Various observers at different times have attempted to determine what has been called the mechanical equivalent of light—namely, how much energy is it necessary for a source to radiate per second in order to produce 1 c.p. of light. From the foregoing it is obvious that the mechanical equivalent of light must vary with the nature of the source. As a result of a recent determination, C. V. Drysdale "On Luminous Efficiency and the Mechanical Equivalent of Light," Proc. Roy. Soc., A, 80, 1907-08, p. 19), using glow lamps, obtained 16·7 candles per watt for yellow-green light.

The visibility is greatest for green light. This, consequently, is the cheapest kind of light; but, being monochromatic, it is of no use for the purpose of discriminating colour. The ideal illuminant must make all colours appear the same at night as by day. It might be possible to make a creditable white light by combining two monochromatic sources, but for making all colours appear the same by night as by day the illuminant must have all the colours of the spectrum in the same proportion as average sunlight. Consequently, we arrive at the specification of the energy curve of the perfect artificial illuminant after which technology is striving. *Throughout the visible spectrum it will have an energy curve like that of average sunlight; the energy curve will cease at the limits of the visible spectrum.*

(To be continued.)

Simmer Pan Power Station.—The June "Transactions" of the South African Institute of Electrical Engineers, which have only recently come to hand, contain a brief description of this power station, the members of the Institute having paid an official visit to the station on July 15th last. The party was received by the chief engineer, Mr. Bernard Price, who is vice-president of the Institute.

THE BRITISH ASSOCIATION AT PORTSMOUTH.

(FROM OUR SPECIAL CORRESPONDENT.)

Wednesday, August 30th.

The eighty-first meeting of the British Association commenced this evening at Portsmouth, when Sir William Ramsay, K.C.B., F.R.S., delivered his Presidential Address in the Town Hall. In requesting Sir William to take the chair, Prof. Bonney, the outgoing President, referred to his great work in radio-activity, and said that he might be said to have brought down helium from the sun to earth by showing that it was all the while lurking in various terrestrial substances.

Since the new President's address has already been published in THE ELECTRICIAN, there is no necessity to refer further to it here except to say that it was warmly received by an appreciative audience. The Mayor of Portsmouth moved a vote of thanks to Sir William Ramsay, and at the same time extended a hearty welcome to the British Association on the occasion of its first visit to Portsmouth. Prof. Dixon seconded the motion, which was carried with acclamation.

Thursday, August 31st.

Work commenced in real earnest this morning when the respective Presidents of Sections opened the proceedings by reading their addresses. Reference has been made already to Prof. H. H. Turner's address to Section A, and there is nothing of electrical interest in Prof. J. H. Biles's address to Section G.

After a vote of thanks to Prof. Biles had been proposed by Sir William Ramsay, seconded by Mr. Alexander Siemens, and carried unanimously, Mr. Worby Beaumont read his Paper on "The Origin and Production of Corrugation of Tramway Rails." The author contended, as will be seen by the Paper which we publish on another page, that the primary cause of corrugation is really a triple one: (*a*) The great weight of the cars, (*b*) the small diameter of the wheels employed, (*c*) the high speeds at which cars are run. These three factors together, he maintained, are such as to render it impossible to procure any material which will not be deformed under the stresses put upon it. As a result of experiments, conducted at the request of Mr. Fell, on certain London County Council equipment, he came to the conclusion that the pressure between wheel and rail, in the case of driving wheels, rose as high as 100 tons per square inch when the car was rounding curves, and in the case of pony wheels it was even 120 tons. Hence, it is evident that the pressure per unit area exceeds the limit of elastic compression of the material of the ordinary rail, and that flow or deformation would occur if it were not that the area pressed is supported by the surrounding material and held *encastree*, so that flow cannot occur. The result is detrusion of both edges of the rail, but, of course, the inner is ground down by the flange of the rail. Another result is that the material of the rail moves forward with the advancing wheel until it becomes so compressed and hardened that the wheel mounts it, making it harder still, and then begins to make another depression on the other side. A third result is the minute crumbling and pitting of the rolled surface. Mr. Beaumont put forward four suggestions for dealing with the difficulty. The first was to reduce the weight of the car; this would have the effect of reducing the pressure between the tyre and the rail. He did not observe, nor did any speaker in the discussion which ensued, that decreasing the weight of the car would have the effect of decreasing the area of contact, and, therefore, to some extent, defeating its own object, since pressure is equal to force divided by area. His second suggestion was that larger wheels should be used; this, of course, would increase the contact area and therefore reduce the pressure. Speed reduction was his third point, and the use of harder material for the rails his fourth. With regard to this latter, however, he admitted that harder rails would necessitate the employment of methods more costly than those now in use.

Mr. Alexander Siemens opened the discussion, and said he could scarcely imagine that Mr. Beaumont believed his conclusions to be possible—viz., that the speed of cars should be reduced and the wheels made larger. He thought Mr. Beaumont was quite wrong to suggest harder rails; his own opinion was that they should be softer or, at all events, more elastic. This would secure a much larger area of contact by permitting the wheel to sink in as it were. Directly the wheel moved on the nature of the rail material would cause the depression to disappear. He suggested that rails should be made of hard material with a tread of soft or elastic material on the top. Sir William White said that corrugation was experienced on gun-beds due to the motion on recoil; this, however, had been overcome after lengthy experiments had been carried out, but he did not divulge the nature of the experiments. He did not agree with Mr. Siemens that the rails should be made of softer material. After one or two other speakers had interpolated remarks, Mr. Beaumont replied to the discussion. He asserted, with due respect to the President of the Institution of Civil Engineers, that Mr. Siemens had devoted very little study to the use of tramway materials if he could advocate the employment of soft rails, and in reply to a protest from Mr. Siemens he (Mr. Beaumont) said he thought Mr. Siemens meant ductility when he said elasticity. The question of speed reduction was a very difficult one, and would remain so owing to the fact that a tramcar was bound to keep to the rails. The consequence was that a high speed had to be attained whenever a clear course was available in order that the average speed could be kept up to the desired magnitude. He thought it would be quite possible to employ larger wheels, but at the same time he recognised that this would lead to a considerable modification in the design of cars. Corrugation was becoming a very serious matter, for it raised the cost of repairs and renewals to such a figure as to make some tramway systems financially impossible without aid from the rates. Moreover, the noise and vibration were becoming almost unbearable. He did not think it possible to do anything with the wheels or tyres so as to make the latter elastic, and thereby increase the area of contact with the rails.

The next Paper on the list was on the "Anschutz Gyro Compass," by Mr. G. K. B. Elphinstone. This device, as its name implies, is a gyroscope, carried on a float which rests in an annular vessel of mercury, the centre of mass of the whole arrangement being brought about 4 in. below the surface of support. Its action is entirely independent of the earth's magnetic field or of the presence of magnets or iron in the neighbourhood. The rotating element is electrically driven, and the air current set in motion by it is employed for damping purposes. The combined action of gravity and the earth's rotation is such as to cause the gyroscope always to point to the geographical north. Mr. Elphinstone showed a model compass, while in an adjoining room several instruments were exhibited. There was no discussion on the Paper, as time had slipped away, and it was one o'clock when the author finished.

In the afternoon a visit was paid to the Dockyard, and the visitors were shown over H.M.S. "St. Vincent." This visit was the occasion of a good deal of grumbling among members of the Association at the lack of organisation apparent. Association officials seemed to be conspicuous by their absence, and this may have accounted for the fact that very little of interest was seen. Our attention was directed to the wireless aerial, but we were informed that no one could be allowed to look inside the operator's cabin. Only by persistent efforts did a chosen few manage to get down to the engine room. This is divided into two distinct portions and it is necessary to go up to the main deck in order to get from one to the other. The ship is driven entirely by turbines of the Parsons type, the condensers being of the surface type. When running at full speed, the coal consumption works out at about 1·5 lb. per horse-power-hour, but when running at half speed the coal consumption goes up to about 3·5 lb. It appears that, by an Admiralty order, the turbines may not be opened up within five years from

Digitized by Google

their installation. The gun-laying is carried out by hydraulic power and ammunition hoists, &c., are similarly worked; electric motors are, however, employed for ventilating.

In the evening a reception was given by the Mayor and Mayoress on the South Parade Pier.

Friday, September 1st.

After a discussion on the principle of relativity, Section A divided into two portions, one of which proceeded to listen to Papers on Mathematics and the other on General Physics. The first Paper in the latter category was "On the Radiation producing Aurora Borealis" by Mr. L. Vegard. Starting from the view advocated by Birkeland that auroræ are caused by electric solar radiations, the author treated the problem of determining their physical properties. From the form and structure of the luminosity a method is found of examining the way in which the solar rays are absorbed by matter, and he arrived at the conclusion that the law of absorption of the solar rays is essentially the same as that of α-rays. This coincidence with regard to law of absorption led the author to draw further consequences of the hypothesis that certain auroral forms are caused by α-rays. The author finds that the α-ray hypothesis, as far as our present knowledge goes, explains in a satisfactory way the properties of the definite auroral forms, while the assumption of a radiation of the β-ray type meets with serious difficulties.

The next Paper was entitled "A Friction Permeameter," by Mr. W. H. F. Murdoch. This we hope to publish in next week's issue of THE ELECTRICIAN.

Section G opened with a Paper on "Electrical Drives for Screw Propellers," by Mr. H. A. Mavor; the Paper is dealt with elsewhere in this issue. The author advocated the employment of three-phase working, and gave details of several installations in actual operation. It seems that high-speed propellers give very poor results on low-speed vessels, and hence a difficulty arises if it is desired to employ economical high-speed engines. In the case of turbines the problem resolves itself into a choice between mechanical gearing and what may be regarded as electrical gearing. Mr. Mavor described systems in which engines were employed for driving three-phase generators, the motors being connected directly to the propeller shafts. By this means very large speed reductions could be obtained with a trifling loss of power. Opening the discussion, Prof. W. E. Dalby asked for efficiency figures at full and half loads. He also inquired whether there were not serious flywheel effects obtained by connecting a motor of some 12 ft. in diameter to the propeller. Prof. Petavel suggested that the high efficiency obtained might compensate for the losses in transmission. At the same time he could not help thinking that additional liability to breakdown was introduced by the presence of the dynamo, motor, &c., as well as the engine, which had to be there in any case. Dr. J. Morrow said he thought that the electric drive might be very suitable for low-speed ships, but he was not convinced that it could be applied with advantage to high-speed vessels. He also suggested that the U.S. Navy authorities were discarding turbines in favour of reciprocating engines, but Sir William White at once explained that only in in the case of one slow-speed vessel, now building, were they putting in a reciprocating engine, and, therefore, Dr. Morrow's statement was hardly accurate. The chairman, Prof. Biles, asked whether short-circuiting would take place if the motor were flooded, and if so what would happen. In his reply, Mr. Mavor said that the full load efficiency was about 96 per cent., but that, as a rule, he preferred to work with large air-gaps and amply proportioned machines, the result being that the efficiency worked out at about 90 per cent. Although he had had considerable experience with large motors directly connected to propellers he had detected no trouble due to flywheel action, as suggested by Prof. Dalby. He quite agreed that it was useless to talk of electric driving if the propeller could be driven by the engine, but the fact remained that a low-speed ship could not be driven by a high-speed propeller. If electric driving were adopted there was nothing to prevent the use of an engine running at 3,000 revs. per min. in a low-speed ship. In a particular instance he had obtained an estimate from makers of mechanical gear, and it turned out to have practically the same weight, price and efficiency as the electrical gear. There was no additional danger of breakdown because there was practically no additional complication. Nothing could be simpler than a squirrel-cage rotor, and he called attention to the fact that the energy was generated in the stationary portion of the machine, it was transmitted by cables that did not move, and it was utilised in the stator of the motor. It was sometimes more economical to employ two or three small generating sets, rather than one large one, as they were frequently more efficient. Moreover, each machine could be connected to its own coils of the motor, and was, therefore, completely independent of the others. Complicated switch-gear was avoided, and since the motor coils were mutually non-inductive there was no fear of current being generated back into a machine which happened to be at rest. With regard to the chairman's suggestion of short-circuits, he pointed out that even if a short-circuit did occur it could have no serious consequences. The power of the engine was limited, and the only effect would be the production of a current two or three times greater than the normal, with a corresponding drop in voltage. This would produce nothing like the disastrous results associated with short-circuits on street mains designed for comparatively small currents, when there was practically unlimited power at the generating station. So far as he could gather, flooding of the motor did not make the least difference. Some time ago he made an experiment on an old continuous-current motor, which, of course, possessed the additional disadvantage of a commutator; this machine he put under water, and it ran quite sweetly all day. In reply to Sir William White, Mr. Mavor said that the voltage he employed was 2,000, but the pressure was quite immaterial.

The next Paper on the list was on "Electrical Steering," by Mr. B. P. Haigh. The problem is a difficult one because two very different conditions have to be fulfilled. On the one hand, it is necessary to have a system capable of dealing with the power necessary to put the helm hard over in emergency in the shortest possible time, and, on the other, it must possess sufficient sensitiveness to enable an accurate course to be kept by moving the rudder promptly through small angles. So far as sensitiveness is concerned, it appears that electrical gears are an improvement on steam gears, partly owing to the rapid wearing of valves and the loss of economy when large sensitive valves are employed. In the author's system the motor is kept running and is provided with two magnetic clutches, one at each end of the shaft. Three slip-rings are provided on the motor shaft, one being common to both clutches and the others distinct. Current is carried from the slip-rings to the clutches by means of leads passing through a hole in the shaft. These leads are quite small, the magnetising current being only about ½ ampere. The actual friction surfaces in the clutches consist of steel and red fibre.

The discussion was opened by Mr. Worby Beaumont, who thought that there would be considerable inequality of performance of the fibre employed in the clutch; he also thought it undesirable to carry leads in the motor shaft. Sir William White expressed himself strongly in favour of electrical steering. He had recently designed a yacht in which everything was done by electricity. He rather thought that great sensitiveness of steering gear was sometimes a positive disadvantage, for it tempted a steersman to manipulate it much too frequently; indeed, it might even be a source of danger in the hands of a nervous person. For this reason, he strongly advised the installation of a helm indicator in every case so that a steersman could see the immediate result of his movements. He would abolish all hunting gear, and give all orders from amidships. So far as sensitiveness and ease of control were concerned, the superiority of electric gear was undoubted. Prof. Dalby, who spoke next, said that the principal feature of Mr. Haigh's device was the clutch. He would like to know what was the coefficient of friction between the steel and fibre, and what was the pressure per square inch

Digitized by Google

In the course of his reply, Mr. Haigh said fibre was the best substance he had tried. The difficulty with wood was that it soon charred, and then made an intolerable squeaking noise. Fibre, of course, was very hygroscopic, and on this account would prove unreliable when the clearance was small, the clearance on his clutch being $\frac{1}{16}$ in. He had, however, got over the difficulty by boiling the fibre in oil, which effectually prevented any absorption of moisture. There was no appreciable slipping even when oil was present. He had purposely poured oil into the clutch and then closed it; for about a dozen revolutions it slipped, then the oil was squeezed out between the fibre segments, and it held quite well. He had not noticed any falling off of friction with temperature, nor was there any variation when the rudder was hard over. The power demanded by the motor was not sufficient to affect the lighting circuit. He did not think there was any danger incurred by putting the leads in the shaft of the motor. Very sensitive gear was never put on low-speed ships. In reply to Prof. Dalby, the author stated that the coefficient of friction of steel on fibre was about one-sixth, and the pressure he employed did not exceed 100 lb. per square inch.

Mr. T. F. Wall next read a Paper on "The Single-phase Repulsion Motor," but as it was of a type seldom heard at a British Association meeting, there was no discussion. It will be given in full in future issues of THE ELECTRICIAN.

Next came a Paper entitled "Some Preliminary Notes on a Study as to Human Susceptibility to Vibration," by Mr. W. Pollard Digby and Capt. A. Riall Sankey. The Paper described the results undertaken with a view to ascertaining what amount of vibration can be said to constitute a nuisance. The audience treated the matter as something in the nature of a joke, and some additional "standards of degree of vibration" were suggested informally. Apparently, certain members seemed to think that "excessive" was not a sufficiently violent adjective to describe some forms of nuisance, and although they did not put them forward at the meeting there is no doubt that many would be prepared to offer suggestions to the authors with a view to adding to the different degrees. Prof. Dalby said he thought no subject should be treated who had not just completed three months' holiday. Sir William White thought there must be some scientific standard of vibration; the human element varied so greatly as to make it quite hopeless otherwise. Prof. Petavel called attention to the effect of sound, which made observers think a vibration very much more serious than it really was.

The chairman then announced that Prof. E. Wilson had asked for his Paper on "Some New Aluminium Alloys" to be taken as read, and this concluded the business of the day. (This paper will be given in next week's issue of THE ELECTRICIAN.)

Monday, September 4th.

Sections A and G had a joint meeting this morning for the purpose of discussing "Aeronautics," and then split up again. The first Paper on the programme for Section G was by Prof. J. W. O. Howe, on "Recent Developments in Radio-telegraphy," and it attracted a large audience. The author gave an excellent, though brief, account of the modern practice of wireless telegraphy, and succeeded in making some difficult points quite clear by means of diagrams. Moreover, he had erected up an aerial from the Town Hall to the roof of the Municipal Technical College, in which the meeting was held, and was able to receive—among other things—the Paris and Norddeich time signals. By means of a telephone relay of the pattern designed by Mr. S. G. Brown and conical trumpets these signals were made audible to almost everyone in the room. Prof. Howe's Paper is published in full in the present issue of THE ELECTRICIAN, and we will, therefore, refer to it no further here.

Next on the list came a Paper by Capt. H. Riall Sankey, entitled "Portable Equipment for Wireless Telegraphy." However, instead of reading a Paper Capt. Sankey contented himself with showing a number of quite interesting slides relating to portable sets for use by troops in the field. The first set was intended for cavalry, the various parts being carried on the backs of horses. For example, one horse carried the petrol engine and alternator, another the sending and receiving apparatus, while a third carried the mast and aerial. The capacity of the alternator was 0·4 kw., and the range was 20 miles over mountainous country and 100 over water. Each animal's equipment was securely fastened to a saddle of special design, and in no case did the total weight exceed 180 lb. When fully extended the mast had a length of 60 ft., but as a directive aerial was employed it was necessary to carry two masts, the effective length of aerial being 350 ft. between masts. In order to preserve the insulation of the high-tension transmitting apparatus the latter was completely enclosed in a metal case. On taking this case from the horse's back, a double lid is opened, one serving as a writing desk and the other as a protection against rain, &c. Capt. Sankey mentioned that the time occupied in getting a station set up and working was only nine minutes, while the time occupied in taking it down and packing it up again was six minutes.

At the conclusion of Capt. Sankey's remarks there was only about a quarter of an hour available for discussion of both Papers, owing to a fixture having been arranged for 2 p.m., but even this proved more than sufficient. In reply to questions from Prof. Dalby, Prof. Howe stated that the Marconi trans-Atlantic work was carried on with a wave-length of 6,000 metres. He had ascertained this from his own observations. The minimum that he knew of was 300 metres, and he believed that the Admiralty kept all wave-lengths between 600 and 1,600 metres for themselves. The sharp tuning of the receiving station depended on the tuning of the transmitting station, for if the coupling were too tight, harmonics came in; it was impossible to tune to an explosion. This concluded the work of the Section for the day.

In the afternoon a most interesting display was provided by the Admiralty, by arrangement of the Commander-in-Chief, Admiral Sir A. W. Moore, G.C.B. Members of the Association were taken on board H.M.S. "Revenge" at the Dockyard and sailed out to sea some miles from the coast. An attack was then made on the vessel by about a dozen torpedo boats. These boats advanced on the "Revenge" at full speed, discharging torpedoes at her as they passed alongside. Next, four submarines advanced in line ahead, the first passing with conning tower out of water and driven by her petrol engines. The second advanced and dived just as she came alongside, this vessel and the remainder being driven by electric motors. The third dived gradually as she passed, and reappeared after passing. Finally, the fourth boat, which could be seen rather more than a mile away, dived and advanced on the "Revenge" with only her periscope showing. When she got within striking distance she fired a torpedo which gave the onlookers a decided thrill, as it struck the vessel with a plainly perceptible "bump." Still advancing, she fired a second, and then dived so that even her periscope disappeared. In a few seconds she reappeared, and her commander, who presently emerged from the conning tower, was greeted with a storm of applause. The "Revenge" then returned to the Dockyard, and members were unanimous in describing the display as quite the feature of the Portsmouth Meeting.

Tuesday, September 5th.

Some very interesting work was done in Section G this morning, when the respective merits of steam, suction gas and Diesel engines were discussed. Mr. W. T. Marshall commenced with a Paper on "Economical and Reliable Power Generation by Over-type Superheated Steam Engines." He remarked that owing to the introduction of internal combustion engines, steam-engine builders had been stimulated to produce steam plants having a fuel cost quite on a par with that of internal combustion plants, and possessing additional advantages in the nature of superior reliability, flexibility and over-load capacity. The so-called "over-type superheated steam engine" is a distinct reversion to the old portable type, and consists of a compound engine fixed on top of a tubular boiler, with a superheater in the smoke box. Air pump, feed

Digitized by Google

pump and other auxiliaries are attached to the side of the plant, and it is claimed that by this arrangement steam pipe losses are reduced to a minimum, while the full value of superheated steam can be employed. The author described in detail a plant of this type now being manufactured by Messrs. R. Garrett & Sons, of Leiston, Suffolk. The boiler is of the Cornish multi-tubular type, with a single circular furnace, and heating surface consisting of smoke tubes, through which the products of combustion pass. A special feature is that by means of a bolted joint between the ends of the furnace ring and the front end plate, and another between the back tube plate and the back end plate, the whole of the furnace and tube system can be readily withdrawn for cleaning and inspection. Saturated steam passes to the superheater, which consists of a number of zig-zag coils of solid drawn steel tubes expanded into cast-iron headers, and so arranged that the flow of steam is in the opposite direction to the flow of hot gases, thus ensuring maximum efficiency. The superheater itself can be easily withdrawn for cleaning. From the superheater steam passes to the engine, which is a side-by-side compound engine, fitted with piston valves to the high and low-pressure cylinders. The cylinder casing forms a steam jacket for both cylinders, the actual working barrel or liner of the cylinders being made of special cylinder metal pressed into this casing hydraulically. The engine is governed by varying the cut-off in the high-pressure cylinder, a crank-shaft governor operating upon the high-pressure piston valve. From a test on a 50 B.H.P. Garrett engine, it appears that the coal consumption was as low as 1·21 lb. of coal per brake-horse-power-hour. The author claimed that the cost of fuel per brake-horse-power-hour with the superheated steam engine is very nearly constant over a wide range of loads, and does not increase on light loads to anything like the same extent as with the suction gas engine.

Mr. Marshall was immediately followed by Mr. W. A. Tookey with a Paper on "Suction Gas Engines and Producers." Mr. Tookey explained that his Paper consisted of a series of figures representing the actual performance of suction gas power plants of various types and different powers, not only when tested by some form of brake dynamometer, but also when the output over the period of test could be measured by the generation of electric current or by the raising of water, thus taking into account the combined efficiencies of the electric or pumping machinery and that of the gas power plant. With regard to the oft-quoted pound of fuel per brake-horse-power-hour, the author's figures showed that it was often as low as 0·7 lb. to 0·85 lb. per brake-horse-power-hour.

The third Paper was by Mr. Chas. Day, on "Diesel Engines." The author opened with arguments against the selection of an engine being made on makers' guarantees of fuel consumption, as such guarantees could not possibly cover all working conditions. Thus, an engine which gave best results on tests might give inferior results over a long period in normal working, when items such as wages, repairs and maintenance were included. It was urged that judgment should be based on records of actual working results which included all items of expenditure, and it was pointed out that, owing to the power costs of electricity supply stations being kept on a uniform basis, these formed the best available data on which to judge the working results obtained with different types of plant. He agreed that the conditions of working in some factories differed considerably from those of an electricity supply station, but claimed that loss of efficiency was largely brought about by causes common to all places, and that consequently deductions from electricity station figures were applicable to the great majority of power cases. Stations having a plant capacity exceeding 1,000 kw. were excluded from the main comparisons. The following table gives Mr. Day's results :—

Average Cost in pence per B.T.U. Sold.

Type of engine.	Fuel.	Lubricating oil, waste, stores and water.	Wages.	Repairs & maintenance	Total works cost.	Load factor.
Steam	0·45	0·06	0·25	0·26	1·02	14·7
Gas	0·43	0·09	0·28	0·24	1·04	15·3
Diesel	0·23	0·04	0·19	0·07	0·53	14·3

With regard to efficiency at different loads, the author quoted the following figures: Full load, 0·44 lb. of fuel per brake-horse-power hour; three-quarter load, 0·45 lb.; half load, 0·47 lb.; ¼ quarter load, 0·62 lb. He was convinced that makers' tests and working tests were of no practical use for purposes of comparison; the only way was to take the average results over a number of years. With regard to reliability he quoted a case where, during four years, the average running time of a Diesel engine worked out at 23·75 hours out of every 24. The discussion on all three Papers was then commenced.

Capt. H. Riall Sankey said he would like to know on what basis the various engines were rated. This was an important matter because people bought engines on the basis of so much money per horse-power. Was it what the engine *could* do for, say, a quarter of an hour, or was it, as in the case of steam engines, the most economical load with an overload allowance of 20 per cent. or 30 per cent? Mr. Day's figures of fuel consumption for the Diesel engine at different loads, given above, corresponded to those of a steam engine, but the fuel consumption of a suction gas engine got much worse as the load decreased. He then drew a diagram on the board, based on Willan's law, to illustrate this, and pointed out that a gas engine of 125 H.P. would be required to perform the same work as a steam engine of 100 H.P., both ratings being based on fuel consumption under steady continuous load.

Prof. W. E. Dalby remarked that the reciprocating steam engine had been free from competition for 100 years, and now it had to face, not only the steam turbine, but the suction gas engine, the Diesel engine, &c. In his opinion, the only way of salvation for the small reciprocating steam engine was by the adoption of superheated steam. He wanted to know, however, whether, in the Garrett engine, superheated steam went right through both high-pressure and low-pressure cylinders or only through the former? Also, was it possible to cut-out the superheater? There was no doubt that very substantial economy had been effected by the use of superheated steam on locomotives. The secret of the advantage was that superheated steam was a bad conductor of heat, whereas saturated steam was a good one; it was a purely physical explanation.

Mr. E. Kilburn Scott was opposed to the suction gas engine as against either the steam or the Diesel engine. He did not like the gas. At all events, nothing could be raised from water but steam; the nature of producer gas, on the other hand, was an uncertain factor. Moreover, an escape of steam was plainly visible and did no great harm, whereas an escape of carbon monoxide could not be seen and was a very dangerous thing. He cited a case within his own personal experience where a suction gas plant was thrown out because a man had been "gassed"; the risk of having to pay a large sum by way of compensation for the death of a workman was too serious. He was strongly in favour of the Diesel engine. In steam plants there was always the trouble of the steam raising plant, with all its complication of pipes and valves. Practically there was no limit to the size of an engine and dynamo, but there was a very distinct limit to the size of a boiler, and the result was that the steam raising plant had to be split up into a large number of small units occupying a disproportionate amount of space. Then there was the water difficulty; generating stations had frequently to be built on extremely expensive sites merely because it was impossible to obtain water elsewhere. He did not like the idea of the superheater—it was too complicated. None of these disadvantages attended the Diesel engine, and he was sure there was a great future for its application to the generation of energy for electro-metallurgical processes.

Mr. H. E. Wimperis alluded to the fact that superheated steam was really a gas and could be condensed when it was desired to get rid of it. Herein lay its great advantage over suction gas, which could not be condensed. Moreover, it could be produced from a cheap common liquid. The future competition would be between what might be called internal combustion engines and external combustion engines, and he looked with confidence for the introduction of an internal combustion turbine which would be driven by superheated steam. He could not understand why some Diesel engines were made

Digitized by Google

substantially; they gave one the impression of being armour-plated. With regard to the intricacy of the Diesel engine, he often refrained from recommending its adoption abroad where only unskilled native labour was available. Did Mr. Day see any prospect of its being as easy to look after by unskilled labour as the suction gas plant?

Capt. Sankey here remarked that he had before him, at that moment, a proposition for using superheated steam as a gas.

Mr. H. S. Russell called attention to the fact that the low costs of the Diesel engine depended on the load factor; its fuel costs were lower because there were no stand-by losses, and it had a high thermal efficiency. He thought Mr. Tookey's stand-by losses much too low, and instanced a case of a 500 H.P. suction gas plant being taken out owing to a breakdown, and replaced by a Diesel engine. It was subsequently found that the comparative costs in the two cases were 0·7d. per unit for the suction gas plant and 0·3d. per unit for the Diesel engine. Actual experience showed that while the working costs of a Diesel engine were about 14 per cent. in excess of the maker's guarantee, the working costs with a superheated steam plant were about 140 per cent. in excess. He had known of a case where a Diesel engine installed as an auxiliary on a battleship had run for 800 hours without stopping. There must be a saving in wages, because separate men were required in the producer house or boiler room, while this was not so with the Diesel engine. The latter also required about 0·2 gallons of water per brake-horse-power hour, against 2 gallons for suction gas.

Prof. Marchant called attention to the capital charges involved, and said he did not think sufficient regard was paid to these in the course of the discussion.

In his reply, Mr. Marshall explained that the rating of the engines depended on the boilers. He affirmed that a 140 H.P. engine would have practically the same efficiency between that load and 180 H.P., while its overload capacity would reach 200 H.P. for as long as six hours. He did not think Mr. Day's comparison of fuel and wages costs quite fair, because some of the steam engines in electricity stations were very old and uneconomical. Steam in the Garrett engine was superheated 150°F., making the final temperature 500°F. to 600°F. He did not think there was any superheat in the low-pressure cylinders, but the exhaust steam was quite dry.

Mr. Tookey, in his reply, said that the rating of gas engines was settled by commercial considerations. At the present day the rating was that of the maximum power which the engine was capable of working at, no matter how short that period might be. He preferred to ascertain the horse-power by calculation and assuming that 4 cubic ft. of piston displacements were required per minute for every brake-horse-power developed.

Mr. Day replied that the Diesel engine was rated on its steady working capacity. The master patent had expired, and in order to indicate the extent to which the engine is being manufactured, he said that no fewer than 30 firms had started to make it in Germany within the last three years. On going to a small town to try and open up business in connection with it, he found that five firms were already producing it. With regard to the difficulty of native labour, his experience was that the engine which was least known was the best run by native labour. The African negro was no good, but the Chinese coolie was excellent. The latter did what he was told and kept things clean; he did not form theories, and think he could improve the valve setting. He (Mr. Day) did not agree with Mr. Marshall about the age of steam engines in electric generating stations.

Wednesday, September 6th.

A Paper by Mr. E. Kilburn Scott, on "The Manufacture of Nitrogen Compounds by Electric Power," was first on the programme in Section G this morning. The author described several of the different types of "furnace" employed in the fixation of atmospheric nitrogen by electricity for the purpose of manufacturing artificial manures. In the Birkeland and Eyde process the nitrogen is fixed directly from the air, and the nitric acid produced then reacts with carbonate of lime. In the calcium cyanamide process the nitrogen, after being isolated from the air, is absorbed by calcium carbide. The author then drew attention to the manufacture of nitrogenous products for explosives, and enlarged on the desirability of some steps being taken by the nation to ensure a good supply of such nitrogenous products in time of war. He maintained that we were at present entirely dependent on supplies from Chili, and that if private enterprise would not provide for manufacture at home then the Government should do so. There was no doubt that power could be produced cheaply enough if only sufficiently large units were employed. The trouble in the past had been that we had been trying to produce cheap power with small units, and he referred to the number of small municipal stations scattered about the country, which he described as "tin-pot." Mr. Scott spoke at some length on the evils of municipal electricity supply, but the relevancy was hardly apparent. Ultimately, he reverted to the subject matter of his Paper, and concluded by expressing the hope that the matter would be taken up seriously in this country at no distant date.

Sir William Ramsay, in opening the discussion, agreed that coal costs in England were now low enough to enable Mr. Scott's proposals to be carried into effect. He advocated large electric power stations with chemical works adjoining.

The next speaker in the discussion was connected with some large works in Norway, which have actually been working for some time. On nearly every point he expressed disagreement with Mr. Scott. At present there was no chance in England; it had been gone into by people who knew, and they were convinced that the time was not ripe. A very high state of development had, however, been reached in Norway. They had a factory in course of construction on the Continent which would have a capacity of 250,000 kw., and the first half of this was practically completed. The works that Mr. Scott had referred to were only of an experimental nature, and there were many difficulties yet to be overcome. Hence the wise thing to do was to wait and secure the results of Continental experience. He disagreed with the author about national danger; the Government would not take up any process while it had the Navy to protect the Chili fleet. Sir William White said he agreed with the author regarding cost of generation in England. Only four or five years ago an eminent Swiss engineer, giving evidence before a Parliamentary Committee, had said that it was cheaper to generate by coal than by water-power, even in Switzerland. If this was the case, there could be no doubt about it in England, where generating stations could be built in situations convenient for coal supply. Electricity in bulk could be produced more cheaply here than in any other country in the world. He thought Mr. Scott need not go so far as Chicago for examples of cheap generation by large units; he need go no further from home than Newcastle-on-Tyne. With regard to the national question, he thought it a great advantage to any country to have powers of production within its own borders, without relying upon supplies from outside. Prof. Petavel called attention to the low figure of 3 per cent. which the author said was the proportion of energy actually utilised; he thought it should be possible to increase this. Some years ago he had been engaged with Dr. Hutton on experiments, the object of which was to ascertain the effect of increased pressure within the furnace, and it was found that there was an increase in the percentage yield. The pressure employed was as high as 3,000 lb. per square inch. Mr. H. E. Wimperis said he had calculated that there must be something like 1,000,000 H.P. going to waste from blast furnaces and coke ovens; if this were utilised the fuel costs would be very low. Mr. Scott then made a few remarks in reply.

The next Paper was one of considerable interest, entitled "Smoke Abatement" by Dr. John S. Owens. After showing the futility of the present legal standard of "black smoke of such quantity as to be a nuisance," the author pointed out how utterly inadequate existing methods of dealing with the trouble were. Even the best methods suffered from the defect of failing to take into account the diameter of the chimney. He,

Digitized by Google

the author, had devised an instrument in the form of a telescope with a rotating diaphragm in the focus of the eye-piece. This diaphragm was mounted eccentrically with the axis of the telescope, but in it were pierced six circular apertures, each, when in position, being concentric with the axis. In each aperture was placed a semicircle of smoked glass, but the density of the smoking was varied according to the order of the aperture; that in aperture No. 2 was twice as dense as that in No. 1, and so on. If the density of No. 1 were taken as a standard for a particular diameter of chimney, then No. 2 would be used for a chimney of twice the diameter. The instrument enabled observations to be made by one person from almost any point, and the same background was available both for the smoke and the glass. What he asked for was the appointment of a responsible committee to fix a standard. The Paper was followed by a very brief discussion.

The last item was a Paper by Mr. W. Y. Lewis on "Continuous *versus* Intermittent Service in Passenger Transportation." This related to a proposal to do away with the intermittent train system in traffic, such as that encountered in tube railways, and to substitute a system of small cars running continuously and at comparatively short distances apart. These cars, however, were to be propelled by means of a gigantic screw engaging with rollers on the cars, and the great feature was that the pitch of the thread was to vary at points corresponding to stations about ¼ mile apart. Hence cars would always be in motion, but they would move more quickly between stations, and sufficiently slowly at stations to allow of passengers getting on and off. Moreover, in the course of being retarded they returned energy to the driving system. A letter was read from Capt. H. Riall Sankey saying that he had seen the system at work, and that the average acceleration obtained was about 4·5 ft. per second per second. From tests made something like 80 per cent. of the energy taken out by the car on acceleration running was put back on retardation. Mr. H. E. Wimperis remarked that it was not great acceleration which caused discomfort to passengers, but great rate of change of acceleration. He had observed that this quantity was sometimes as great as 20 ft. per second per second per second on stopping. In his reply, Mr. Lewis said that there was no intention of trying to instal the system on existing tube railways, but they hoped to put it in fresh ones, especially as it was found that an ordinary electric train service could not be made to pay if the stations were less than ½ mile apart. The new system had an efficiency of 90 per cent., and it was peculiarly suited to the working of lifts.

This concluded the work of the Section for the year. Next year the Association meets in Dundee under the presidency of Prof. E. A. Schäfer, in the following year at Birmingham and in 1914 in Australia.

A NEW TWO- TO THREE-PHASE TRANSFORMER.*

BY DR.-ING. M. VIDMAR.

Summary.—The system of transformation described in the following is employed by the Gesellschaft für elektrische Industrie at Weiz bei Graz for interlinking their old two-phase supply with a modern three-phase system. The author compares it with the Scott system, and shows that it is an improvement on the latter both as regards weight and cost, and also by the fact that the leakage, and therefore the voltage drop, is smaller.

The new transformer consists of a three-limbed iron core, similar to a three-phase transformer, but with special dimensions and special windings.

Considering first the transformation from a three-phase system to an interlinked two-phase system, we have, to start with, the three points A, B and C (Fig. 1) of the pressure triangle of the three-phase generator. The primary winding—that is, the three phase—is normal in so far as each winding is wound wholly on one core only, but the three phases do not have equal numbers of turns. Two phases, placed on the outer cores for the sake of symmetry, have the same number of turns, but the third has a different number, the value of which has to be determined. The transformer is connected star. Denoting the number of turns of the three phases by w_1, w_2, and w_3, we then have

$$w_1 = w_2 = w \gtrless w_3 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

Considering now the triangle A B C in Fig. 1, we see at once that the back E.M.F.'s induced in any two phases must balance the pressures between the corresponding angles of the triangle.

Also the pressures in the two equal phases must be equal, and therefore the flux in their cores must also be equal. Moreover, if these two pressures are displaced by an angle a (Fig. 1), which is unknown as yet, the fluxes will be displaced by the same angle.

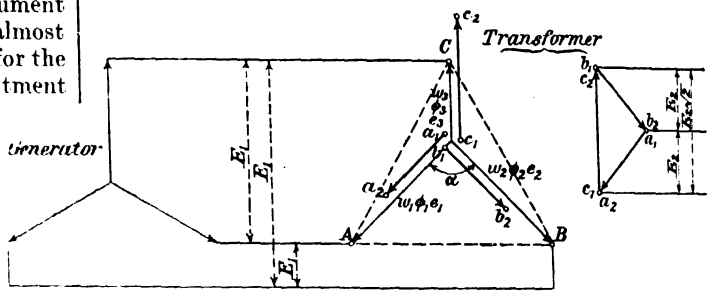

Fig. 1.

To obtain equilibrium, the flux in the third core must be equal and opposite to the resultant of these two equal fluxes.

The following symbols will be used :—

e_1, e_2, e_3 = the three phase pressures,
Φ_1, Φ_2, Φ_3 = the corresponding fluxes,
F_1, F_2, F_3 = the cross-sections of the three cores,
k = a constant,

and we can write

$$e_1 = e_2 = e. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

$$\Phi_1 = \Phi_2 = \Phi. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3)$$

The equation for magnetic equilibrium is

$$\Phi_3 = 2\Phi \cos \frac{a}{2} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4)$$

while the corresponding electrical equations are

$$E_1^2 = e^2 + e_3^2 + 2ee_3 \cos \frac{a}{2}, \quad . \quad . \quad . \quad . \quad . \quad . \quad (5)$$

and

$$E_1^2 = 4e^2 \sin^2 \frac{a}{2}, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (6)$$

Now

$$e = k\Phi w \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (7)$$

and

$$e_3 = k\Phi_3 w_3 = 2k\,\Phi\, w_3 \cos \frac{a}{2}. \quad . \quad . \quad . \quad . \quad . \quad . \quad (8)$$

Hence, from equations (5), (6), (7) and (8) we obtain

$$\frac{w}{w_3} = \frac{1 \pm \tan \frac{a}{2}\sqrt{3}}{1 - 2\cos a} 2\cos^2 \frac{a}{2}. \quad . \quad . \quad . \quad . \quad . \quad . \quad (9)$$

If now, according to the extended Kirchhoff's law, the current

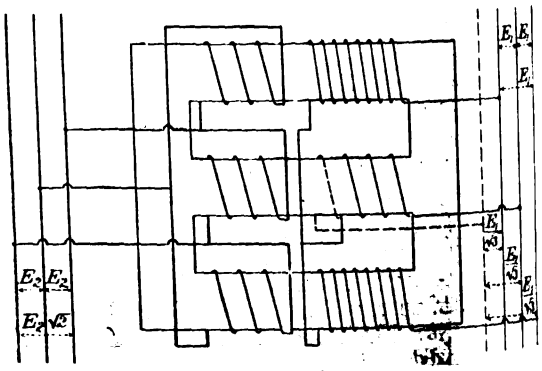

Fig. 2.

polygon of the three magnetising currents closes in the star point, the flux-densities in the three cores must be chosen to correspond. Hence we must make

$$F_1 = F_2 = F$$

and

$$F_3 = 2F \cos \frac{a}{2}, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (10)$$

in which F_3 can be taken slightly less than the above value, to allow for the dissymmetry of the core.

Equation (9) shows that any phase-displacement can be obtained between the two pressures e. If $a = 90°$, $\frac{w_3}{w} = 0{\cdot}366$, which is characteristic of this new transformer.

* Abstract of an article in "Elektrotechnik und Maschinenbau."

Digitized by Google

Hence from equation (10) we have

$$F_3=\sqrt{2}F_1=\sqrt{2}F_2.$$

Passing now to the secondary—that is, the two-phase—side, the windings on the two outer equal limbs must have equal numbers of turns, since these produce the phase pressures of the two-phase system which are displaced by 90°. The winding on the third limb is connected in mesh with these two and arranged as shown in Fig. 2. The two outer wires of the system are connected to the middle coil and the middle wire to the common point of the two outer coils.

The third winding plays an important part in this transformer. Its duty is specially clear in transforming three-phase into uninterlinked two-phase currents; it carries equalising currents, the properties of which will be shown later.

To find the ratios of the numbers of turns on the two-phase side, it is clear that the pressure polygon must close, since the system is connected in mesh. Hence the pressure induced in the third winding must be $\sqrt{2}$ times the phase-pressure of the two-phase system. Since, however, the middle limb carries $\sqrt{2}$ times as much flux as the other two, the windings on all three limbs must have the same number of turns.

We will now proceed to find the ratios of transformation of the three cores, which we will denote by u_1, u_2 and u_3. Denoting the interlinked three-phase pressure by E_1, and the phase pressure on the two-phase side by E_2, we have

$$e=\frac{E_1}{\sqrt{2}},$$

$$e_3=0{\cdot}366E_1,$$

and therefore

$$u_1=u_2=u=\frac{E_1}{\sqrt{2}\,E_2} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (11)$$

$$u_3=\frac{0{\cdot}366E_1}{\sqrt{2}\,E_2} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (12)$$

The next point to consider is how a balanced non-inductive load on the two-phase side is transferred to the three-phase side. Magnetising currents and pressure drops will be neglected.

Where the outer wire enters the transformer, the current branches into two parts, one part passing to the other outer wire through the equalising winding. This current I_3 is as yet unknown both in phase and magnitude. Together with the load current J (Fig. 3) it forms the current I in the windings. Making use of the law of superposition, we now consider that the two currents J flow undisturbed to the

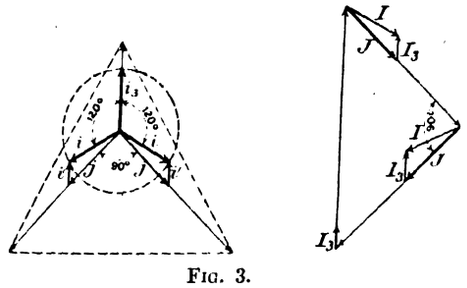

FIG. 3.

middle wire, while an equalising current flows through the whole mesh.

Considering the balance of the M.M.F.'s in the two outer primary cores, the currents

$$j=J\,.\,1/u \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (13)$$

must flow, displaced 180° from J.

Also in the same cores we must have

$$i_1'=i_2'=i'=I_3/u \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (14)$$

and in the middle core

$$i_3=I_3/u_3=I_3/0{\cdot}366u \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (15)$$

To determine the value of I_3, we will use the extended Kirchhoff's law for the primary star point. The three current vectors must form a closed polygon, or in other words, the resultant of i', i', j and j must be equal and opposite to i. Since, however, the resultant of j and j falls in the direction of the phase pressure of the middle core and since i' and i_3 have the same phase, it is clear that i_3 must also fall in in the same direction (Fig. 3).

We will now proceed to determine the magnitude of i_3.

The resultant of i', i', j and j is equal to

$$j\sqrt{2-2i'},$$

which is the magnitude of i_3.

Hence from equations (14) and (15) we obtain

$$\frac{I_3}{0{\cdot}366u}=\frac{J}{u}\sqrt{2-2\frac{I_3}{u}},$$

or

$$I_3=J\sqrt{2}\,.\,0{\cdot}366/(1+2\,.\,0{\cdot}366)=0{\cdot}299J, \quad . \quad . \quad . \quad . \quad (16)$$

and further

$$i_3=1/u\times 0{\cdot}815J. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (17)$$

Calculating now the values of the other two equal currents on the three-phase side, we have

$$i^2=j^2+i'^2-2i'j\cos 45°$$

or, using equations (14) and (15),

$$i_1=i_2=i=1/u\times 0{\cdot}815J \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (18)$$

and therefore equal i_3.

We see from this that the current polygon formed by i_1, i_2 and i_3 is closed and, since the three currents are equal, forms an equilateral triangle. Hence the three currents are displaced from each other by 120°. One of these, i_3, is known to be in phase with its phase pressure and hence it follows that a balanced non-inductive load on the two-phase side is also balanced and non-inductive on the three-phase side. The energy equation

$$2E_2J=\sqrt{3}i\,E_1$$

in conjunction with equation (11) gives us

$$i=\frac{\sqrt{2}}{\sqrt{3}}J\frac{1}{u} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (18a)$$

which checks with equation (18).

In a similar manner to the above a balanced inductive load can be shown to be transformed into a balanced load with the same phase-displacement.

It is also easy to show that the Scott system as well has the above advantage. The leakage of the latter, however, is greater than that of the new transformer, for the two halves of the primary winding by themselves produce a leakage flux, since they partly oppose each other.

Proceeding to examine the properties of unbalanced loads, we see that such a load can be considered as a superposition of a balanced load and a load in one of the three phases. Hence we need only consider this load in one phase.

For this we must obtain the star-point of the three-phase system.

The pressure induced in the middle winding is equal to

$$e_3=(\tfrac{1}{2}\sqrt{3}-\tfrac{1}{2})E_1,$$

and the phase pressure of the three-phase system is

$$E_{ph}=E/\sqrt{3}.$$

Hence by winding on the middle core

$$w'_3=w_3\frac{1/\sqrt{3}}{(\frac{1}{2}\sqrt{3}-\frac{1}{2})}$$

turns instead of $w_3=0{\cdot}366w$, we obtain the star-point (Fig. 2).

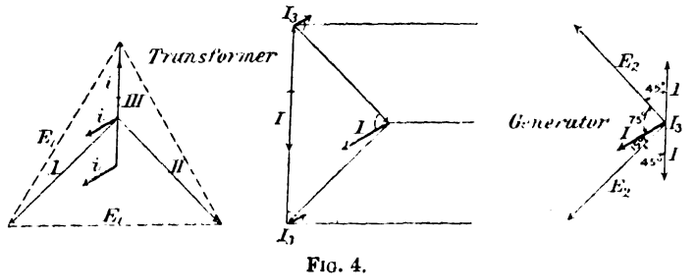

FIG. 4.

We now find two different kinds of load, according to the phase in which it occurs. In one case the load current i traverses the winding on one core only and in the other case windings on two cores.

A non-inductive load in phase III. (Fig. 4) can easily be investigated.

Considering the balance of the M.M.F.'s, the winding on the middle core on the two-phase side carries a current

$$I=i\frac{1/\sqrt{3}}{\frac{1}{2}\sqrt{3}-\frac{1}{2}}\,0{\cdot}366\,.\,0{\cdot}707E_1/E_2$$

or

$$I=i\frac{E_1}{\sqrt{3}\,.\,E_2}0{\cdot}707$$

The current I flows in both phases of the generator and is displaced 45° from its phase pressure, which is shown by re-writing the above equation

$$2E_2\,I\cos 45°=iE_1/\sqrt{3}.$$

Treating the Scott system in the same way, it can be shown that only one phase of the generator is loaded but with purely watt current. The copper losses in the generator are thus the same with both systems, but in the Scott system, they are not distributed so favourably as in the new transformer. Moreover, the two-phase system is largely distorted with the Scott transformer, apart from the far greater reactances of the same.

The second case is obtained by loading phase I. or II. (Fig. 4). The load current then flows through a part of the middle winding as well as one of the outers and thus induces a current in the equalising winding on the two-phase side.

Digitized by Google

The primary currents are now equal to

$$I = i\,0{\cdot}707\,E_1/E_2$$

and

$$I_3 = i'\left(\frac{1/\sqrt{3}}{\frac{1}{2}\sqrt{3}-\frac{1}{2}}-1\right)0{\cdot}366\frac{E_1}{E_2}0{\cdot}707$$

or

$$I_3 = i\,0{\cdot}707\,\frac{E_1}{E_2}\,\frac{0{\cdot}366}{\sqrt{3}}.$$

Considering now the directions of the currents, we obtain the following two load currents in the two phases of the generator :—

$$J_1 = I - I_3 = i\,0{\cdot}707\,E_1/E_2\,(1 - 0{\cdot}366/\sqrt{3}).$$

at 15° to its phase pressure, and

$$J_2 = I_3 = i\,0{\cdot}707\,\frac{E_1}{E_2}\,\frac{0{\cdot}366}{\sqrt{3}}$$

with a displacement of 75°.
Hence we have

$$E_2 J_1 \cos 15° + E_2 J_2 \cos 75° = E_1 i/\sqrt{3}.$$

Examining the similar case for the Scott transformer, we find that the copper losses are again equal, but in both systems badly distributed, so that now the Scott system is slightly the better.

We will now consider the problem of the conversion of three-phase current into uninterlinked two-phase and vice versa, a procedure which is at once possible with the Scott system, but presents some new features with the new transformer. For this purpose it is necessary to separate the winding on the middle core, which carries the equalising current, so that it is not connected with the two phases.

We have treated the problem above by means of the principle of superposition and have first considered the two load currents to flow in their windings and then superposed the equalising current I_3 flowing in the closed circuit formed by the two-phase side connected in mesh.

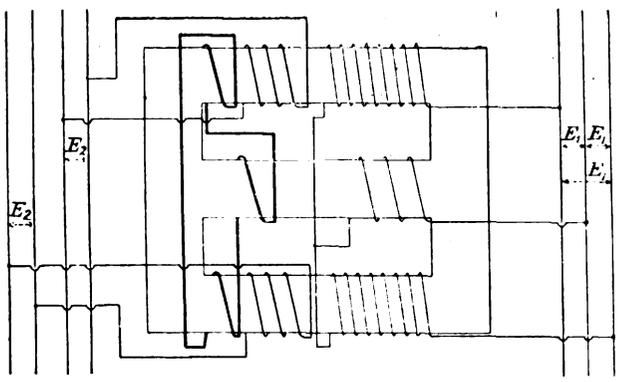

FIG. 5.

This condition is also possible physically, and it is clear that the circuits will have the same relations, if they are arranged as one short-circuited winding and one winding for each phase, which are not connected either to each other or to the short-circuited winding. This arrangement is shown in Fig. 5, and can be called a physical use of the principle of superposition.

Now from equations (15) and (11) we have

$$i_3 E_1 = \frac{\sqrt{2}}{0{\cdot}366} I_3 E_2$$

and we also have

$$E_2 = \Phi k W,$$

where W is the number of turns per limb of the secondary side, which is equal for all three limbs.

The expression on the left of the first of these equations is proportional to the load of the transformer and we can write

$$(I_3 W) k_1 = L \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (19)$$

where L is the load and

$$k_1 = 4{\cdot}44\,\frac{\sqrt{3}\sqrt{2}}{0{\cdot}366} \approx BF10^{-8}.$$

Equation (19) is evidently merely the value of the ampere-turns of the short-circuited winding and since we have no other equation for I_3 or W—with the interlinked two-phase system W depends on E_2—any arbitrary value may be chosen for W, so long as it can be designed for the corresponding current I_3.

Hence W is chosen small, so that there is no high pressure in the equalising winding and so that a good space-factor is obtained.

The chief advantages of the new transformer compared with the Scott system are the following :—

The leakage is considerably less.

The overall dimensions are smaller.

With uninterlinked two-phase current the weight is about equal to the Scott system, and with interlinked two-phase current it is considerably less.

PACIFIC CABLE BOARD.

The accounts for the year ended March 31, 1911, together with the report of the Chairman of the Board, have been issued.

The traffic receipts for the year were £140,313. 2s. 3d., less £4,170.6s.7d. paid to the Atlantic companies for work done and delivering double copies in London and other large centres in the United Kingdom, leaving, therefore, £136,142. 15s. 10d., which, together with interest on deposits (£225. 10s. 2d.), refund tolls and dues (£202. 16s. 3d.) and charter of "Iris" (£2,106. 12s. 3d.), made a total of £138,677. 14s. 6d., leaving £29,334 for meeting the annuity of £77,544 payable to the National Debt Commissioners in respect of interest and sinking fund on the capital advanced for laying and equipping the Pacific cable. This is £11,378 more than was available in 1909-10. The increase of £24,677 in the net traffic receipts was mainly due to increase of business and to receipts from new sources of revenue in the tolls on traffic between Montreal and Bamfield over the line leased by the Board from the Canadian Pacific Railway Co. The revenue of the year was further augmented by £2,106 received from the Eastern Extension Australasia & China Telegraph Co. on account of the chartering of the Board's repairing ship "Iris" for a fortnight in July, 1910. In February and March, 1911, the "Iris" was again chartered for a month by the Cie. Française des Cables Télégraphiques, for repair of the New Caledonia cable, and the extra expenditure on that occasion fell on the account for 1910-11, although the payment from the company was not received within that year. Thus the extra receipt of £2,106 was fully counterbalanced in the account for the year by increases on the expenditure side of the account. In the opinion of the Board it is not desirable to treat as current revenue the whole of the extra receipts derived from the chartering of the "Iris" on occasions of this kind, and it is proposed to balance extra receipts representing profit on a charter of the "Iris," by adding in the year affected a corresponding sum to the fixed sum of £30,000 now carried annually to reserve.

Expenditure for the year shows an increase of £15,576. This is almost wholly accounted for by the cost of the new Canadian land line service and the extra charges in connection with the hirings of the "Iris." But additional charges have also been incurred in respect of the annual increments to salaries, and of sundry requirements incidental to an expanding service. At the same time the working expenses, while showing an advance of over £15,000, fell short of the estimate by some £5,000. This was due to the fact that the actual taking over of the Canadian service was delayed to a later date than the Board had anticipated.

The preliminary forecast of revenue and expenditure for the year ending March 31, 1912, prepared on Dec. 7, 1910, was: Traffic revenue £141,000; renewal fund £30,000 and working expenses £80,975, excess £30,025. The renewal fund stood at £264,236 on March 31, 1911. No interruption of communication occurred on the Board's system during the year. The several sections of the cable, the depots, instruments and plant generally have been maintained in a high state of efficiency, with the single exception of the electrical condensers. These have shown somewhat serious deterioration due to climatic influences, and it has been found necessary to undertake repairs and renewals on a comprehensive and systematic scale. The process is an expensive one, and during the next year or two, during which the old condensers will be renewed or replaced, an extra expenditure of some £250 per annum will be entailed.

The arrangements for transferring to the Board's management the service over the section of the Canadian land lines between Montreal and Bamfield were completed in September last, and from Oct. 1 were brought into full operation. The results have been entirely satisfactory. As regards times of transmission the records show that in the three months October to December, of last year, the average time per message between the United Kingdom and Sydney was reduced by 15 minutes, compared with the three months June to August, and between the United Kingdom and Melbourne by 18 minutes.

The cable ship "Iris" has been maintained in first-class order, and the discipline and efficiency of the permanent officers and crew has left nothing to be desired. On three separate occasions during the year the "Iris" had to be ordered to sea. On no one of these was there found to be any difficulty or undue delay in completing her complement, or in getting her ready for sea, and the experience of the year has satisfied the Board as to the policy of maintaining only a skeleton crew during the times when the vessel is not actively engaged. The health of the staff during the year has given no cause for anxiety, and the zeal and efficiency have been fully maintained.

Following the reductions in Press rates to which reference was made in last year's report, the Board authorised a reduction from 3½d. per word to 2¾d. per word in the rate for Press messages between Bamfield and Fiji. At the same time they reduced from 1d. to ¾d. per word the charge on Press messages to Australia that are "dropped" at Fiji. These changes came into operation on Sept. 1 last, and constituted the only actual change made in rates during the year. But a prospective change of general and great importance—viz., the establishment of a system of allowing messages not of immediate urgency to be sent at reduced rates—has been the subject of prolonged consideration and negotiation. In May, 1910, the Board drew up a scheme for giving effect to this principle in the case of traffic passing over the Pacific cable. The Postmaster-General discussed the proposals with the British and American cable companies, and, after obtaining their approval of them, entered into negotiations with foreign Governments. As a result, such a measure of general agreement has been reached that there is every prospect that within the next few months it will be possible for messages in plain language to be sent at half the existing rates of charge, subject only to the condition that the transmission of them must await, for a period not exceeding 24 hours.

COMMERCIAL AND INDUSTRIAL SECTION.

MUNICIPAL, FOREIGN & GENERAL NOTES.

BRITISH NOTES.

Brighton.—An interesting report on methods of charging for current, meter rent, &c., has been prepared for the Lighting Committee by Mr. John Christie, the engineer and manager of the electricity department.

In his report Mr. Christie points out that the Council should aim at having the simplest tariffs and one flat-rate of 1d. per unit, common to all classes of consumers, with special discounts to exceptionally large users, instead of the existing three rates. At present there are the maximum demand system of 6d. and 2d. per unit; a 3d. flat rate for hotels, licensed premises, clubs, &c.; and a 4d. flat rate for shop lighting and domestic supply. 80 per cent. of the consumers have reverted from the maximum demand system to the flat rates, and the remaining 20 per cent., who still elect to be charged on the maximum demand system, are obtaining their supply at a lower average price than they would get if they changed over to either of the respective flat rates to which they are entitled. To protect themselves against a serious loss upon such a transition as adopting one standard flat rate, Mr. Christie suggests that the policy be adopted gradually, the first step being to abolish meter rentals; next, gradually reduce the flat rate for shop lighting and domestic supply from 4d. to 3½d., then to 3d. per unit, and finally reducing the common flat rate of 3d., a little at a time, to such a figure as to induce all the maximum demand consumers to discard the system for the flat rates. The adoption of such a suggestion would involve a reduction in the current year's revenue equivalent to about £600. The concession would assist them in developing the undertaking, especially among the smaller householders, and he was assured of its ultimate success. The complete abolition of meter rentals would involve a loss of revenue of £1,200 per annum, and, although possibly for a few years increased business would not directly compensate for the loss, it was the only concession which they were able to afford at present, and must be regarded as a concession to which private consumers had some claim as a result of the satisfactory working of the undertaking during the last few years. The cutting off of supply between 5:30 p.m. and 8 p.m. during December and January, prevented a number of prospective customers from using the electricity, and those restrictions, too, would have to be abolished. Last year 173,576 1½d. units were sold, yielding £1,084. If the concession was granted Mr. Christie estimated that the loss would be £361, but increased business on the part of breweries, laundries, &c., would neutralise that. For outside consumers Mr. Christie suggested a reduction of charging to one flat rate of 1½d. per unit. The present tariffs are: For first 250 units used during each half-year, without restriction, 2d. per unit; from 250 to 500 units, 1¾d. per unit; and over 500 units 1½d. per unit. The revenue from the 3,757 units distributed outside the Brighton area last year was £30. 3s. 9d., and the reduction would make a difference of £6. 14s. 1d., which would quickly be wiped off by increased business.

The committee, having considered Mr. Christie's suggestions, recommended that they be approved by the Council and acted upon, and that the tariff of charges for the supply of electricity approved by the Council on April 16, 1908, be amended accordingly; also that from Oct. 1 the existing charges for meter rents be abolished except in cases of consumers upon the maximum demand system.

Darwen.—The Board of Trade recently suggested that speed indicators should be fixed on the tramcars, but the Tramways Committee have postponed action in the matter until the Association of Tramway Managers have interviewed the Board on the subject of speed indicators generally.

Eastbourne.—A rebate of ¼d. per unit is to be made to consumers whose supply exceeds 40,000 units per annum.

Electric Ambulances in Dockyard Work.—The Port of London Authority propose to supplement their first-aid agencies at the London docks by four electric ambulances, which are at present being constructed.

The electric ambulances will be employed for the areas of the Victoria and Albert, the Surrey Commercial, the London and the West India Docks and the estimated cost of the service per year is about £4,000.

Electrical Exhibition, Olympia.—The management of this exhibition will send any contractors pictorial posters of the exhibition on hearing from them, and on consideration of such contractors exhibiting these bills in their windows, they will be entitled to two complimentary tickets to the Exhibition. It is therefore hoped that contractors will assist in giving the Exhibition every publicity.

Electricity in Agriculture and Horticulture.—It was recently announced by the Board of Agriculture that the sum of £50,000 per annum was to be allotted by the Development Fund Commissioners for agricultural research and other work in connection with the development of agriculture and horticulture. There is a general impression that some portion of this large annual vote will be allocated to experiments in connection with the application of electricity to the acceleration of crop growing, and there is a likelihood of the State in this way helping the efforts of Mr. J. E. Newman, Sir Oliver J. Lodge and Mr. Lionel Lodge in their practical work in the Evesham district of Worcestershire, where much has been done to demonstrate the possibilities of this scientific advance.

Exhibition of Patents.—London is to have a permanent exhibition of patents which will be situated in a central position, and will be open to the public all the year round. There will be no charge for admission, the object being to establish a centre where inventors may display their patents for attracting the attention of purchasers. Particulars from the administration office, 165, Fleet-street, E.C.

Fire.—A fire broke out on Sunday at the works of the North of Scotland Electric Light and Power Co., Inverness. Damage to the extent of about £1,000 was done to the stores and plant, but supply of current was not interfered with.

Garvagh (co. Londonderry).—Arrangements have been made for the public electric lighting of this village by 14 25-c.p. metal filament lamps. Electric current will be supplied by Mr. Stewart.

Glasgow.—The Parliamentary and Tramways Committees have adopted recommendations of a sub-committee to obtain parliamentary powers to construct certain new tramways and to erect a new bridge over the Clyde from South Portland-street to St. Enoch-square. The proposal that the tramways be extended from Canniesburn Toll to Milngavie, and from Baillieston to Coatbridge, was not approved.

Greenock.—The Electricity Committee recommend a reduction in the price of electric current for private lighting from 4d. to 3½d. a unit and for public lighting from £15 to £14 per arc lamp per annum. The price of energy for power is also to be reduced.

Ilkley.—On Wednesday the Council decided to apply for a provisional electric lighting order for the urban district of Ilkley and the township of Myddleton.

Lighting of German Trains.—It is announced that in future passenger coaches of the Prussian railways will be lighted by electric light instead of gas. The Rosenberg system of electric lighting has been adopted.

Llandudno.—Application has been made for sanction to a loan of £500 for extensions of mains, &c.

Llangollen.—The Council have been advised that the transfer of their provisional electric lighting order to the Llangollen & District Electric Light & Power Co. is not legal, and a committee has been appointed to consider the situation.

Local Authorities and Fair Wages.—The L.G. Board have issued a circular to County and Town and Borough Councils, &c., drawing attention to the recommendation of the Advisory Committee of representatives of Government Departments with reference to the "fair wages" clauses in contracts.

The circular, which was signed by the secretary (Mr. H. C. Monro) and was accompanied by a copy of the "fair wages" clauses, stated that "the accompanying memorandum embodied the resolution passed by the House of Commons on March 10, 1909, on the subject of fair wages clauses in Government contracts, and the recommendations made by the Advisory Committee of representatives of Government Departments, which had been established as suggested in para. 124 of the report of the Fair Wages Committee of 1908. It would be seen that the Advisory Committee recommended that clauses such as those inserted in Government contracts should also be introduced into contracts which were not entered into by Government departments, but which involved the expenditure of public money or other consideration granted by a Government department, or which required the approval of the department. It appeared to the Board that the policy adopted in the case of Government contracts should be followed in the cases of all contracts for the execution of works or the supply of materials which are entered into by local authorities or by or on behalf of any committee wholly or in part appointed by a local authority. Whilst they are aware that many local authorities specify in their contracts conditions to be observed by the contractor as to the rates of wages and other matters affecting persons employed by him, the Board think that in every case the authority should give the matter careful consideration with the view to the introduction in the contracts of clauses on the lines of those inserted in Government contracts.

Digitized by Google

L.C.C. Tramcar Accident.—An accident occurred on Saturday afternoon to a L.C.C. tramcar at the junction of Shardeloes-road and Lewisham High-road, resulting in the death of one person and injuries to several passengers. The car left the rails and was overturned.

An inquest was held on Tuesday, when a verdict of accidental death was returned, and on Wednesday a Board of Trade inquiry was conducted by Col. von Donop.

JARRETT, the driver of the car, said he thought if he could have got the car to stop it might have righted itself. The magnetic brake did not act when applied, but he thought the jerk of the car before overturning showed it had just then come into action and then skidded. He afterwards examined the rails, and found a quantity of hard sand in the groove He was certain it was not the sand he had released.

REEVE, the learner who was on the car, said that where the wheels left the rails the lines were full of old dirt. He did not connect the dirt in any way with the derailment. The magnetic brake failed to act, but he could not account for it in any way.

Evidence was given to show that the state of the track at the place of the accident was good and that the condition of the car and its brakes was normal before the accident.

Ormskirk.—The Council have sealed the agreement for the transfer of their provisional electric lighting order to the Ormskirk Electric Supply Co. Mr. J. W. Speight is consulting engineer to the company, which proposes to establish electricity supply in the district at an early date.

Pontardawe.—Messrs. Gilbertson & Co. are prepared to erect poles and supply electric current for public and private lighting, provided their position is made legal, and the Sanitary Committee has, therefore, been requested to consider a form of agreement to be entered into with the company.

Presentation.—On Friday the staff of Sheffield Tramways Department presented a silver tea-tray to Mr. H. E. Yerbury, chief engineer, on his marriage with Miss Dorothy Wood.

Mr. E. J. MARSH, chief electrical superintendent, in making the presentation, conveyed to Mr. Yerbury the congratulations of the staff on the happy event and mentioned that Mr. Yerbury had been on the department since the commencement of the electrification of the tramways. Mr. A. Handford, the traffic superintendent, and Mr. J. R. Williams, superintendent of the power station, also spoke.

Salford.—The borough electrical engineer (Mr. H. J. Hawkins) has prepared a report upon the present position of the electricity works, in which he recommends the installation of modern turbine plant and the scrapping of the existing reciprocating engines, one at a time, as required.

Mr. Hawkins puts the cost of carrying out his recommendations, which would increase the capacity of the works to 12,000 kw., at £85,350. The recommendations include the modernisation of the coal-hauling plant at an estimated cost of £3,100; displacing (as required) eight existing boilers by seven water tube boilers, £14,000; additional turbo-generator, £12,500; removing existing store and fitting shop, and erecting travelling crane for turbo plant, £750; new fitting shop and store, £1,500; extending switch room and building new switchboard, £3,500; replacing one at a time four 750-900 kw. engine sets by turbo-generators of 1,600 kw. at a cost of £12,500 each turbo-generator, £50,000. The increased capacity of the plant would reduce the capital expenditure per kilowatt from £90 to approximately £54.

Shoreditch (London).—The Lighting Committee have reported on a proposal to substitute metal filament lamps for the 1,055 gas lamps in streets north of Old-street.

The capital cost of laying about 14 miles of cables in 160 streets, of sufficient size to serve not only for street lamps but to meet any additional demand likely to arise, is put at £8,385, and the cost of converting the street lamps for electric lighting at £665. The scheme would make it not only possible to give supply of electricity to any occupier within the large area proposed to be dealt with, but there would also be a saving to the general rate of about £230. Although some of the streets in which it is proposed to lay mains are of a type not likely to require an immediate supply of electricity for power and lighting, a large number contain small factories, and are in neighbourhoods where new works are likely to be erected. It is proposed to lay mains in the ordinary side streets of sufficient capacity to supply power up to 25 H.P., or 350 50 c.p. lamps, and in the smaller streets mains sufficient to provide 6 H.P. or 84 50 c.p. lamps. The Committee recommend that this proposal be carried out at the sums mentioned, the work to be done gradually.

The Committee have also decided to adopt, as an alternative to the maximum demand system, a flat rate for electrical energy for power of 1¼d. per unit for all supplies of not less than 1,250 units per quarter, with a load factor of at least 10 per cent., and with a scale of discounts varying from 5 to 20 per cent., according to quantity. Where current is used for factory lighting equal to 5 per cent. of that taken for power a further discount of 2½ per cent. is to be allowed off power rate. For power supplies with a load factor of at least 10 per cent., the maximum price is to be 1·5d. per unit, and where the load factor is less than 10 per cent. 2d. per unit. Where factory lighting is equal to 5 per cent. of total used for power the rates per quarter are: 6,250 units and over, 2·5d. per unit; 5,000 and under 6,250, 2·75d. per unit; 3,750 and under 5,000, 3d.; below 3,750, 3·25d. Factory lighting where electric power is not used, 3·25d. per unit; public street arc lighting, 1·5d.; lighting public offices, 3½d. For current used for trade and testing purposes in electrical showrooms, 2·5d. per unit.

Stockton-on-Tees.—The Council are carrying out extensions of the electricity generating plant to provide for next winter's demand.

A contract has been placed with Richardsons, Westgarth & Co. for a mixed pressure turbine combined with a Siemens direct-current 400-500 kw. generator, at an inclusive price of £2,923, to be ready for running in November. The cooling tower is to be extended, the contract having been let to the Klein Eng. Co. The superheater contract has been let to T. Sugden (Ltd.), and the switchgear to Drake & Gorham.

Stourport.—The Council have decided to allow the Kidderminster and Stourport Electric Supply Co. to supply electricity in the district by overhead wires.

Trades' Union Congress.—Mr. W. Mullin, in the course of his presidential address at this year's Trades' Union Congress at Newcastle-on-Tyne, stated that the total membership was now 1,662,133, an increase of 14,418 over last year, and the delegates numbered 523, against 505.

Mr. MULLIN mentioned that since the last congress the Parliamentary Committee had carried out the instructions of the delegates in regard to presenting before Cabinet Ministers the various resolutions agreed to. His experience, as an old member of the Committee, was that those practical talks were of the utmost importance. They stood as the mouthpiece of the trade union movement. The experience of men who knew their subject was laid before the Government heads, and he asserted unhesitatingly that every new measure affecting the working classes before it reached the House of Commons, was influenced and moulded by reason of the views laid through the Parliamentary Committee before the Ministers in charge. The importance of that work increased every year, and was valued alike by whatever Government might be in power. In regard to the Insurance Bill, certain features of the measure called for their careful deliberation. He thought they all understood that any insurance bill that allowed the benefits to be paid to workmen whose share of the contributions were paid indirectly through the taxes of the country, would be a big bar to any effort to improve the weekly wage. The fact that a weekly contribution would be required would cause even the most indifferent to take a greater interest in the measure. One very valuable method of dealing with the administration was by a federation of trades, and he suggested that trade unions, wherever possible, should form themselves into federated groups. The Osborne judgment was still unrepealed, but the Coal Mines Bill had been beaten into shape in Grand Committee. As to the recent series of strikes affecting the transport and railway workers, practically all had been successful in securing advantages hitherto denied to them. Of late years the policy in regard to wages and working conditions had been in favour of mutual agreements, boards of conciliation and the like. It could hardly be said that they had altogether commended themselves in actual working to organised labour.

The Parliamentary Committee reported that it was safe to assert that the Coal Mines and Shops Bills would pass through the House of Commons during the autumn session. Another measure, introduced by the Government with the object of meeting what was known as the Osborne judgment, was also under way. Although, as drafted, it was not so favourable or so comprehensive as trade unionists would desire, it would doubtless be put into satisfactory shape before it reached its third reading. The question of making trade union combinations permanent in their character had occupied the attention of the Committee, and it seemed to them that the State Insurance Bill offered a possible means to that end. The tendency among organised workmen would be to have each separate trade union registered as an approved society for sickness insurance. The Committee, after mature deliberation, were of opinion that it would materially strengthen the unions, and consolidate the trade union movement if the various societies were grouped together into as few groups as possible; that each group should be made the sole channel of receiving and paying the money received from the Treasury for the purposes of sickness insurance; that the duty of administration should, so far as the Treasury requirements admit, be assumed by a representative body elected from each separate group, and that a united and immediate effort should be made to induce the Government to make such alterations in their bill as will admit of these suggestions being carried out.

Workmen's Compensation.—On Wednesday a long resolution on workmen's compensation was passed. In the resolution the Congress condemned the present practice in the appointment of medical referees and claimed that they should be appointed and paid by the State, and should devote themselves exclusively to their duties as referees. That the basis of compensation for all adult workers should be a minimum of 15s. per week where the weekly wages exceed that sum, and full wages when the wages are less than 15s. That in cases of loss of an eye or other permanent injury to body or limbs a fixed sum should be paid irrespective of earning capacity. That all outworkers should be included under the Act on the same terms as factory or other workers; and that compensation should be paid for accidents occurring within the area of the works of any firm to any workman employed in the works or on the premises of his employer, whether or not such accidents happen in the course of the employment of the individual workman.

Tramwaymen's Wages.—*Rochdale* have granted an increase of ¼d. per hour to all employés with over four years' service. This will cost about £500 a year.—*Rotherham* Corporation have also granted

Digitized by Google

an increase of ¼d. per hour to their motormen and conductors. The men will work 54 hours instead of 60, in consequence of the provision of a meal relief, so that their week's wages will be less, although the aggregate expense to the Corporation will be more.

COLONIAL AND FOREIGN NOTES.

Australasia.—The New Zealand "Trade Review" states that the values of imports of electric machinery into New Zealand during the past five years were £187,697, £233,252, £258,851, £212,071 and £207,565 respectively.

The "British Australasian" says Mr. H. R. Harper, the Melbourne city electrical engineer, who recently accompanied the Victorian Premier and Minister of Public Works to Germany and Holland, to inspect the electric railways, will leave England on the 16th inst. and visit the United States with the object of making further observations there, prior to his return to Melbourne.

Ceylon.—The power station at Black Pool is nearing completion.

Chili.—The Government has approved projects (by Don Mario Ibar) for a telephone service in Constitucion, and (by Don S. Correa) for electricity supply in San Vincente (Caupelican).

Customs Duties.—A supplement to the Australian Customs Tariff Guide states that the following import duties will be imposed on telephone parts imported separately :—

Escutcheons, 5 per cent. ad val. (British goods free); round milled brass nuts and bell pillars, 30 per cent. (British 25 per cent.); porcelain bases (fitted), receiver hooks, ebonite or metal knobs, table telephone springs and vibrators (British and other) are duty free.

On shunt coils (imported separately) for arc lamps (British or other), 20 per cent. On main springs used with Morse registers, 5 per cent. (British free).

Under the French Customs tariff (according to recent decisions) the following are the classes under which the articles mentioned are classified: Small electric massage apparatus (524bis., electro-technical apparatus); land portions of submarine cables (535ter., wires and cables, insulated, for electricity). The submarine portions are duty free.

Damascus (Syria).—Mr. E. Weakley, the special commissioner of the Commercial Intelligence Committee of the Board of Trade, writes :—

Although the river Barada furnishes considerable water-power, as many as 150 electric motors (from ¼ to 2 H.P.) are in use for raising water, the motors and pumps being made by a Berlin firm. Damascus agents of British firms have, since 1907, supplied a considerable number of motors in the district. The demand for machinery in the Aleppo district has been insignificant, but the establishment of railway connections with Beyrout has greatly simplified the transportation of heavy machinery, and the introduction of mechanical power has been put on a practical footing. British makers are paying attention to this trade, and have supplied gas, oil and steam engines.

Electrical Schemes for Constantinople.—In connection with the proposal to form an international syndicate to acquire the concessions for the supply of electricity and gas, the equipment of electric tramways, &c., in this city, it is stated that the head office of the organisation (the Consortium of Constantinople) will be at Brussels, and that a limited liability company is to be formed with a share capital of 45,000,000 fr. (£1,800,000), and an equal amount in 4 per cent. debentures.

The board will be composed of representatives of German, French, Hungarian, Belgian and Swiss banks, financial houses and tramway and electrical firms, which have subscribed the capital. Of the capital, 36,000,000 fr. (£1,440,000) is to be devoted to tramways, the same amount for a tube railway, and 18,000,000 fr. (£720,000) to electricity supply and gas. The electrification of the Constantinople tramways and the construction of a submarine tunnel to connect Pera and Galata are public works already secured by the Consortium. The concession for the metropolitan railway has been applied for, but has not yet been granted. The gas and electric lighting will fall under the direct control of the Consortium at a later date, under conditions which have already been fixed.

Japan.—The British Consul-General at Kobé writes :—

The outstanding feature of 1910 was the number of gas plants set up for supplying towns with gas and for small suction gas electric power stations. In the early part of the year the bulk of the orders were given for British machinery, but during the latter half Continental firms secured a number of important contracts, principally by undercutting British prices.

A local rubber electric cable factory, equipped with British machinery and having the services of a British cable expert, has made great progress since last year, and can successfully compete with British goods in price and delivery. As regards quality, time alone will prove. For paper-insulated cables there is still a demand, and large contracts have recently been secured by Continental manufacturers at very low prices.

A report from Formosa states that six electric tower transporters have been ordered from England for Keeling Harbour, and electric capstans are to be erected for moving the cranes along rails on the quays.

The pumps ordered from a British firm for Takow (Formosa) waterworks are to be driven by three-phase electric current obtained either from the Government supply or from an independent station. Practically the whole of the electrical supplies have hitherto come from German and American makers.

Montenegro.—The Government have granted a concession to Mr. A. Dechkovitch for the erection and equipment of two electric power stations, one of 80,000 H.P. capacity at Kolassin, on the Tara river, and one of 5,000 H.P. at Podgoritza, on the Moracha. The former will supply power to an iron mine near Antivari.

South Africa.—The "British and South African Export Gazette" states :—

The early completion of the electrification of the plant of the Durban Roodepoort Deep has been decided upon.

Roodepoort-Maraisburg Council have obtained permission to borrow £8,000 for electricity works, and tenders will shortly be invited for electrical plant and material.

Klerksdorp (Transvaal) Council have reduced the charge for electrical energy from 1s. to 9d. per unit and have decided to advance the money for the wiring of consumers' premises, repayable by monthly instalments with interest at 6 per cent.

Spain.—The "Madrid Gazette" announces that tenders will be opened by the Junta especial de Subastas, Ministerio de Marina, MADRID, on a date to be announced later, for supply of two radio-telegraphic installations, one of a naval type and one capable of being carried by a landing party. The upset price is put at 42,000 pesetas (about £1,550), and a deposit of £80 will be required with each tender. Local representation is essential.

Telegraphic Feat.—The New York "Times" recently made an experiment in order to ascertain the speed at which an ordinary commercial telegraph message could be sent around the world by submarine cable.

The message in question, which was despatched from New York at 7:16:30 p.m. on August 20, was :—"Times, New York. This message sent around world.—Times." The time occupied in transmission over a journey of 28,613 miles (geographical) was 16 mins. 30 sec., including 16 relays, thus giving an average speed of 29 miles a second. The message was transmitted by the Pacific Telegraph Co. from New York to San Francisco, and thence transmitted over the lines of the Commercial Pacific and Eastern Extension Companies, the French Government, Eastern, Europe and Azores and Commercial Companies. The actual route traversed was :—

	Miles.
San Francisco to Honolulu (Com. Cable Co.)	2,287
Honolulu to Midway Island (Com. Cable Co.)	1,332
Midway Island to Manila (Com. Cable Co.)	4,232
Manila to Hongkong (Eastern Extension Co.)	736
Hongkong to Saigon (Eastern Extension Co.)	963
Saigon to Singapore (French Govt. Telegraphs)	630
Singapore to Madras (Eastern Extension Co.)	1,895
Bombay to Aden (Eastern Co.)	1,912
Aden to Suez (Eastern Co.)	1,402
Suez to Port Said (Eastern Co.)	84
Port Said to Alexandria (Eastern Co.)	154
Alexandria to Malta (Eastern Co.)	1,036
Malta to Gibraltar (Eastern Co.)	1,125
Gibraltar to Lisbon (Eastern Co.)	392
Lisbon to the Azores (Fayal) (Europe & Azores Co.)	872
Fayal to New York (Com. Cable Co.)	2,345
Total (nautical miles)	21,397
Equal in land miles to	24,963
Add land lines transmission :	
New York to San Francisco (Postal Telegraph Co.)	3,000
Madras to Bombay (Indian Govt. Telegraphs)	650
Total in land miles	28,613

The fastest previous dispatch was an official message sent by the President of the Commercial Pacific Cable Co. (Mr. Clarence H. Mackay) on the opening of that line in 1903, but on that occasion arrangements had been made to avoid delay. In the present instance it was an ordinary commercial message and no special arrangements were made in regard to its dispatch.

United States.—The city authorities of New York have adopted electric power for driving the pumps of their high-pressure fire extinguishing service. Two electrically-driven pumping stations, with a rated capacity of 3,000 gallons per minute, at a discharge pressure of 300 lb. per square inch, furnish service on every alarm within the high-pressure zone. Pumping by gas power has been found to be cheaper, but water is delivered from the electric pumps at a much higher rate. The outflow of the electric pumps (though rated at 3,000 gallons) averaged 5,000 gallons per minute on the occasion of the great fire of January, 1910, while the gas-driven pumps of Coney Island only averaged 1,450 gallons per minute at the fire of July, 1907.

Venezuela.—Imports to Venezuela during the fiscal year 1909-10 included the following :—

Electrical apparatus and fittings valued at £2,080 (from U.S.A. £1,625, Italy £264, Germany £117, other countries £74); machinery £61,289 (U.S.A. £28,636, U.K. and colonies £17,465, Germany £8,546, other countries £6,642); iron and steel goods, including railway material, £138,177 (U.K. and colonies £51,173, U.S.A. £47,767, Germany £32,348, other countries £6,889); other metal goods £28,038 (Germany £11,265, U.S.A. £7,569, U.K. and colonies £5,543, other countries £3,661).

The British Vice-Consul at Maracaibo states that there are tramways at that town, but there is an opening for further developments in this direction.

Digitized by Google

Wireless Telegraphy Notes.—"The Marconigraph" states that among recent contracts entered into by Marconi's Wireless Telegraph Co. is one with the Crown Agents for the Colonies for the establishment of a station in Ceylon, which will be capable normally of sending a wave length 600 metres in length. In addition, however, with any wave between 1,000 and 2,000 metres, the station will maintain communication with any ship off Madras or with any ship up to a distance of 450 miles over sea (except during periods of severe atmospheric disturbances), provided the ship is fitted with an aerial having a mean height of not less than 100 ft., and suitable receiving apparatus.

According to an American journal, a wireless telegraph station is about to be completed establishing communication between Washington, U.S.A., and Colon, a point at the eastern entrance to the Panama Canal. Near this place is Guantanamo, where the United States is building a vast naval base, and the new station is designed to enable conversation to be arranged and maintained as far east as the Azores, and at least as far west as Washington, a distance of over 2,000 miles. It is stated to be the opinion of naval officers that San Francisco, to the west, and the Eiffel Tower, Paris, to the east of Colon, will ultimately be connected by this station, which has been designed by Mr. R. D. Holliday and is, it is stated, to be equipped with the Fessenden wireless system. The largest of the three towers, of which the station is to consist, will be 600 ft. high, the other two being 450 ft. high. The work of construction is to be carried out by the U.S.A. Navy Department and the officials anticipate that the station will be in operation in 12 months from now.

Mr. Marconi arrived at St. John's, Newfoundland on Friday last. A powerful wireless station is to be erected on Signal Hill, where a number of important experiments will be conducted.

It is announced that the Portuguese Government has decided to adopt the Marconi system of wireless telegraphy, and that stations are to be erected at Lisbon, on the Portuguese coast, and at Cape Verde. "The Times" Lisbon correspondent states that the only point to settle is the question of terms, which, he understands, is to those which have been accepted by the British Government.

ELECTRICITY SUPPLY AND TRAMWAY ACCOUNTS.

Bexhill.—The accounts of the electricity supply department for the year ended March last show capital expenditure £71,828 (increase £3,203), of which £17,680 has been repaid.

Revenue was £10,908 (against £10,244 in previous year), working expenses were £5,834 (£5,157) and gross profit was £5,074 (£5,086). Total costs (including interest and sinking fund) were £10,644 (£9,620) and the net profit was £264 (£624). There are 990 consumers (increase 99) with 46,346 equivalent 35-watt lamps connected (increase 2,996). Maximum supply demanded was 506 kw. (474 kw.). Units generated were 765,271 (690,652), supplied to public lamps 189,102 (167,916), by contract 638 (1,056) and to private consumers by meter 422,713 (393,178). Cost per unit exclusive of capital charges was 0·45d. (0·43d.) of which coal cost 0·55d. (0·63d.).

Dartford.—The accounts of the electricity supply department for the year ended March last show capital expenditure £43,608 (increase £418), of which £10,854 has been repaid.

Revenue was £10,118 (against £9,078 in previous year), working and general expenses were £5,657 (£5,045), gross profit was £4,462 (£4,033); and after meeting capital charges, income tax and expenditure of a capital nature charged to revenue (£434), there was a net profit of £1,032 (£629), which has been placed to reserve.

The report of the engineer, Mr. J. D. Pember, states that the net gain in connections is equivalent to 1,040 30-watt lamps for lighting and 5,100 (=191½ H.P.) for power, the total connections being equal to 35,220 30-watt lamps, or 1,456 kw., including tramway demand. Motors connected amount to a total of 779 H.P. The maximum simultaneous demand for lighting, power and traction was 615 kw. Coal cost 0·48d. (against 0·57d.) per unit sold, total working expenses were 1·07d. (1·15d.), total costs, including capital charges, &c., 1·73d. (1·94d.), and net profit 0·19d. (0·14d.). The average price received (for all purposes) was 1·86d. (1·93d.). The profit is practically all made out of power supply at low rates. The average price for power is 1·44d. (1·63d.). Units sold were 1,266,039 (1,046,615), including 180,699 (164,750) for private lighting, 569,973 (354,105) for power, 123,193 (122,575) for public lighting, and 1,384,174 (405,185) for traction.

Greenock.—The income of the electricity department from private consumers was £30,442 for the year ended May, an increase of £7,510 over the previous year.

The income from tramway supply increased by £133, and the working expenses had increased by £4,379. The gross profit was £17,471, an increase of £3,127. Sinking fund required £5,937 and interest £4,757; and after allowing £970 for depreciation and £504 for Parliamentary expenses, the net profit was £5,520, of which £1,500 had to be carried to reserve. It is proposed that £2,000 be given in relief of general rates and the remainder be placed to reserve.

Halifax.—The accounts of the tramways department for the year ended March last show capital expenditure £400,633 (increase £4,755), of which £317,383 is outstanding

ELECTRICITY SUPPLY TABLES AND DATA.

This Valuable Set of Tables and Engineering Data relating to Electricity Supply and to Electric Traction on Railways and Tramways in the United Kingdom, the Colonies, and some important places abroad, is now ready, and can be obtained complete in handy book form, price 6s. 6d. post free, or on very hard paper for rough or constant use, price 8s. 6d. post free. A complete Index is included.

Revenue was £92,573 (against £89,270 in previous year), working expenses were £60,480 (£54,660), and net profit was £11,514 (£13,066). Passengers carried were 17,057,865 (16,323,755), car-miles run 1,909,397 (1,862,068), and units used 3,608,873 (3,479,464). Total revenue per car-mile was 11·64d. (11·51d.), working expenses, including power, 7·66d. (7·05d.), and average fare per mile 0·77d. (0·77d.).

Handsworth.—The accounts of the electricity department for the year ended March last show capital expenditure £73,478 (increase £1,158), of which £68,095 is outstanding.

Revenue was £8,231 (against £7,813 in previous year). Working and general expenses were £4,152 (£3,806), gross profit £4,078 and net result, after meeting capital charges, a deficit of £555. Total works costs were 0·74d. (against 0·67d.) per unit sold, the increase being chiefly in wages and repairs due to alterations in the tramway service. Coal cost 0·28d. (same as in previous year). There are 532 consumers (increase 109) and 44,769 (38,795) equivalent 8 c.p. lamps connected and 110 (93) motors 577 (479) H.P. Units generated were 1,013,626 (1,033,196), sold for private lighting 241,880 (201,082), for power 278,725 (265,917), for public lamps 132,850 (130,176) and for traction 219,828 (254,255). The maximum supply demanded was 606 kw. (602 kw.).

The report of the engineer, Mr. F. A. Nixon, states that the year under review is the first during which the hiring and hire purchase schemes have been in full operation, and they show a satisfactory result. A tariff of 1d. per unit for heating and cooking was introduced during the year and £57. 14s. 10d. revenue was derived from that source.

Perth (N.B.).—The accounts of the electricity supply undertaking for the year ended May 15 show capital expenditure £60,014 (increase £533), and the amount outstanding is £48,717.

Revenue was £7,892, working and general expenses were £4,920, and gross profit was £2,972. Interest and sinking fund required £2,879, and £150 was placed to reserve, £18 being carried forward. Units generated were 1,035,064 (1,021,935), supplied to public lamps 162,492 (155,898), to tramways 305,371 (309,019), and to private consumers 455,332 (449,042). The total maximum supply demanded was 700 kw. (698 kw.)

The capital expenditure on the tramways is £76,948 (including £22,259 for acquisition of horse tramways), of which £66,530 is outstanding.

Revenue was £8,949, working expenses were £5,428, gross profit was £3,504; and after meeting capital charges and providing £384 for depreciation and renewals, there was a deficit of £1,157. Passengers carried were 1,777,883, car-miles run 251,428, and units used 309,371 (=1·21 per car-mile). Total revenue per car-mile averaged 8·49d., working expenses, including power, 5·18d., and interest and sinking fund charges 4·08d.

Plymouth.—The report of the borough electrical engineer (Mr. E. G. Okell) for the year ended March 31 states that 140 new consumers were connected, making a total of 1,288, and the total connections in 30-watt lamps were 96,276, an increase of 7,169.

The total horse-power of motors connected is 663, an increase of 90 H.P. The total number of units sold increased from 2,456,070 to 2,601,277, there being an increase of 17,000 sold to tramways, 121,971 to private consumers and 6,236 used for public lighting. The works costs for the last three years have been 0·91d., 0·88d., and 0·83d. respectively, and the total cost 1·23d., 1·30d. and 1·22d. per unit, exclusive of capital charges. The cost of coal per unit was 0·5d., against 0·51d. The total expenditure for generation, distribution, management, &c., was £13,202, compared with £13,308, a reduction of £106, notwithstanding the increased output and load. The gross profit (£12,815) represented 8·3 per cent. on the capital. After setting aside £9,848 for interest and sinking fund, the net profit was £2,967, from which £1,797 was taken to meet cost of new meters, services and mains, leaving £1,170 to be applied in aid of rates. There was no addition to capital expenditure, and £1,945 was paid out of reserve towards an expenditure of £2,500 authorised in May, 1909, for turbo-generator, &c., also £145. 9s. (deferred payment for accumulators) was allocated to be met out of the fund in May, 1910.

Sheffield.—The annual report of the manager of the electric supply department for the year ended March 31 has been issued.

There was an increase in total revenue of £10,890, an increase in total costs of £4,370 and in capital charges of £1,067. There was an increase of 3,936,354 in the number of units sold (including 3,804,486 for power) and of 399 in consumers. Practically the whole of the increase in the units sold was for power. For the first time since March, 1908, the units for lighting have exceeded the previous year's sales although the lighting revenue is still slightly less than the preceding year, due to the use of metal filament lamps. The surplus was £3,417. 8s. 3d. on the year's working, compared with a deficit of £2,035 last year. The total costs showed a reduction from 0·555d. to 0·472d. per unit.

The Electric Light Committee recommend strengthening the financial position of the undertaking by transferring a further £5,000 from the accumulated surplus to a renewals fund for the renewal of old machinery, making £20,000 dealt with in this way.

TRADE NOTES AND NOTICES.

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.—The 1911 Edition of the Big Blue Book is READY, price 15s., post free in the United Kingdom, 15s. 9d. The volume brings a great mass of very valuable statistical and technical data quite up to date, and the Directorial Division has been thoroughly revised and amplified up to February 24th.

All branches of Electrical Engineering and Industry are fully treated, and Electro-Financial matters receive every attention in the new volume, which aggregates more than 2,000 pages. The Directory Division is complete and thoroughly accurate, and has been completely revised. The Big Blue Book contains more names of live electrical firms and persons than any other Directory published, and this notwithstanding that all mere lists of members of Societies and Institutions (so easily and cheaply available) are excluded, as unreliable and of little value for Manufacturers' and Dealers' purposes. The full set of valuable Statistical and Engineering Tables, &c., have been very carefully revised and extended, and are now issued in a handy form. These are included in the 1911 Big Blue Book, making it the most complete work of the kind ever published.

TENDERS INVITED.

Tenders are invited up to Nov. 21 for supply of one automatic or semi-automatic switchboard and equipment to the Postmaster-General's Department in WESTERN AUSTRALIA. Tender forms and specifications may be obtained at the Commonwealth Offices, 72, Victoria-street, London, S.W. See an advertisement.

Tenders are invited up to Oct. 18 for the supply of 20 coin-in-the-slot attachments to the Postmaster-General's Department in WESTERN AUSTRALIA. Specifications, forms of tender, &c., may be obtained at the Commonwealth Office, 72, Victoria-street, London, S.W. See advertisement.

The Postmaster-General's Department in SOUTH AUSTRALIA require tenders up to Oct. 25 for supply of cable and paper sleeves. Tender forms and specifications may be obtained from the Commonwealth Office, 72, Victoria-street, London, S.W. See also an advertisement.

The WESTMINSTER ELECTRIC SUPPLY CORPORATION invite tenders for supply, delivery and erection at their Davies-street station of battery boosters and switchboards. Copies of specification, with drawing and general conditions can be obtained from the Secretary of the Corporation, Eccleston-place, Belgravia, S.W., to whom tenders by 10 a.m. of Sept. 12.

Tenders will be received until noon Monday, Sept. 18, for the supply of Swedish, Norwegian, Finland or Russian red fir telegraph poles, for the GENERAL POST OFFICE. Forms of tender from the Controller of Stores, Mr. G. Morgan, Stores Department, G.P.O., 17 and 19, Bedford-street, London, W.C.

ECCLES Electricity Supply Committee require tenders by noon, Sept. 12, for supply and erection of h.t. single phase a.c. switchboard. Specification, &c., from the Borough Electrical Engineer.

PONTYPRIDD Council want tenders by noon Sept. 12 for supply and erection of water tube boiler and Foster superheater. Specification, &c., from Mr. J. E. Teasdel, Electricity Works, Treforest.

MERTHYR TYDFIL Corporation want tenders by Sept. 12 for wiring and fitting the Mardy Hospital buildings. Plans with Borough Surveyor.

SWINTON and PENDLEBURY Council require tenders by Sept. 9 for 12 months' supply of cables, joint boxes, wood troughing, wood covers, bridges and bends, joint box compound and bitumen. Particulars from Clerk.

WISHAW Electricity Department require offers by Sept. 11 for supply of 30,000 pairs of carbons for Oriflame arc lamps burning 12 in series, 480 volts d.c.

Tenders are invited up to Sept. 26 for supply of telephone material and 30 miles of telephone cable, up to Oct. 2 for supply of 10,000 porcelain insulators to Postmaster-General's department in TASMANIA, and up to Oct. 3 for the supply of 42 miles of telephone cable to the Postmaster-General's department in VICTORIA. Tender forms and specifications at the Commonwealth Office, 72, Victoria-street, London, S.W.

The Metropolitan Water and Sewerage Board, Albert-street, BRISBANE, Queensland, want tenders by noon Jan. 30 next for supply and erection of one, two or three complete units, each consisting of power generating plant and pump or pumps to lift not less than 6,000,000 gallons per day. Particulars from the Secretary, and forms from the Agent-General for Queensland.

DUNEDIN (N.Z.) Corporation require tenders by Nov. 1 for supply of (1) 500 B.H.P. vertical type gas engine or Diesel oil engine, suitable for rope driving an a.c. motor and d.c. generator; and (2) direct-coupled vertical type gas engine or Diesel oil engine and d.c. generator (800 kw. at 550 volts). Specification at 73, Basinghall-street, London, E.C.

ANTWERP municipality require tenders by Sept. 14 for electric lighting of a shed on quay 77 of the canal basin. Specification at 73, Basinghall-street, London, E.C.

TULCEA (Roumania) municipality require tenders by Nov. 19 for electric lighting of the town.

Tenders are required for the erection and equipment of an electric power station at the port of VARNA (Bulgaria). Tenders to the Section des Finances of the Railways and Ports Department, Sofia, by 3 p.m. Sept. 30.

NORRKÖPING (Sweden) Harbour Authority require tenders by Sept. 15 for supply of electric windlasses. Specification (in Swedish) at 73, Basinghall-street, London, E.C.

Tenders are invited by the Municipal Council of PELOTAS (Brazil) for a 40 years' concession for the supply of electricity for power and lighting and the establishment and working of electric tramways. Tenders to Senhor Luiz M. da S. Pennafiel, Intendencia Municipal, Pelotas, up to 1 p.m. Nov. 14. A deposit (about £300) is required with each tender, to be increased by the successful tenderer to 25,000 milreis (about £1,670). Further particulars (in Portuguese) can be seen by British contractors at 73, Basinghall-street, London, E.C.

The Municipal Council of BUDAPEST, Hungary, require tenders for the manufacture and supply of plant for a steam-driven electrical generating station, including two groups of three-phase turbo-generators (5,000 kw. each), 10,000 volts 50 cycles, boiler equipment for mechanical output of 5,000 kw. with reserve, pipeline, central switching and accessory equipments, travelling crane for engine room and coal-conveying plant. Specifications, &c., can be obtained at the Presidial Section of the Council, 9: IV., Városház-utca 16, II. 1, Budapest. Tenders by 11 a.m. Sept. 30.

Tenders will be received at the Town Hall, SYZRAN, Russia, on Oct. 14, for the construction of an electric tramway and the supply of electrical energy for lighting.

TENDERS RECEIVED AND ACCEPTED.

The following tenders have been accepted by Salford Corporation: Crompton & Co., continuous-current generator for Ladywell sanatorium, £138. 17s.; Lancashire Electrical Co., system of intercommunication telephones in Town Hall and several departments, £232; Johnson & Phillips, installation of electric light in Health and Water offices, £123. 18s. 6d., and £12 for contingencies.

Warrington Council have accepted the tender of Matthews & Yates for supply of induced draught plant.

The Great Indian Peninsula Railway Co. have placed orders with Greaves, Cotton & Co., Turner Hoare & Co. and H. L. Rochat & Co. (all of Bombay) for lamps, &c., and with W. T. Henley's Telegraph Works Co. for cables, for the illumination of the Victoria (Bombay) terminus during the visit of the King and Queen.

Escher, Wyss & Co. have recently received orders for two 19,000 h.p. tangential wheels, patent oil pressure governors, two pipe lines, valves, &c., for the Rio de Janeiro Tramway, Light and Power Co., four 13,200 h.p. and two 1,000 h.p. high-pressure turbines with governors, for the Tata power works, Bombay, and four 3,000 h.p. and one 100 h.p. turbines, with governors, for the Fuji Cotton Mill, Japan.

Sale by Auction.—Messrs. Horne & Co., 35, Old Queen-street, Westminster, S.W., will sell by public auction at the Royal Arsenal, Woolwich, at 11 a.m. on Thursday, Sept. 21, by order of the Secretary of State for War, some unserviceable and obsolete stores, including quantities of iron, steel, brass, copper, gunmetal, zinc, lead, &c., two vertical engines and dynamos, an electric generator, some

Digitized by Google

engineers' tools, instruments, electric lamps, 8,000 electric lamp bases, &c. Lots may be viewed at the Royal Arsenal, Woolwich, on Monday, Tuesday and Wednesday previous to and on morning of sale. Catalogues from the War Office, Whitehall, the Ordnance Office, Tower, and the Ordnance Office, Royal Arsenal, Woolwich. See also an advertisement.

Plant for Sale.—Mr. Alex. Mein, Station-street, Stratford, London, E., advertises for sale a Crompton three-phase alternator, switchboard, &c.

Fire.—Owing to the outbreak of fire at Ward, Lock & Co.'s premises on 30th ult, Messrs. C. H. Cathcart & Co., 2, Dorset-bldgs., Salisbury-square, E.C., are unable to continue business for a few days and they ask for the indulgence of the trade. The firm would be glad of new sets of lists from all firms who issue catalogues, as the whole of their stock is spoiled.

BANKRUPTCIES, LIQUIDATIONS, &c.

Claims against the Solium Electrical Co. (Ltd.) (in voluntary liquidation) to Mr. E. Harlow, 23, King-street, Nottingham, by Sept. 30.

A first and final dividend of 11d. is payable on Sept. 11 at 191, Corporation-street, Birmingham, to creditors of John D. Carlmark, electrical engineer, 402, High-street, West Bromwich.

BOOKS RECEIVED.

[Copies of the undermentioned works can be had from *The Electrician* office, post free (unless otherwise stated), on receipt of published price, adding 3d. for books published under 2s., and 5 per cent. for books published nett. Add 10 per cent. for abroad or for foreign books.]

"The Transactions of the South African Institute of Electrical Engineers." Vol. II., Part 5. 2s.

COMPANIES' MEETINGS AND REPORTS.

ABERDEEN SUBURBAN TRAMWAYS CO.—At the meeting last week the chairman (Mr. Geo. J. Walker) said that the results of the half-year's working had been satisfactory. They would require in the future to make considerable additions to reserve and depreciation. The new car they had acquired had been of considerable assistance during the summer months, but another car was desirable. A dividend of 2½ per cent. for the past year was declared.

DIRECT WEST INDIA CABLE CO. (LTD.)—The accounts for the year ended June 30 show a profit of £6,323, out of which the directors recommend a further dividend of 3 per cent., making the usual distribution of 6 per cent. for the year, leaving £4,523 to be added to credit of revenue account, increasing it to £36,249.

ELECTRIC SUPPLY CO. OF VICTORIA (LTD.)—The accounts for the year ended March 31 last show a net profit of £11,340, and a credit balance after payment of preference dividend of £7,231.

HALIFAX & BERMUDAS CABLE CO. (LTD.)—The accounts for the year year ended June 30 show a profit of £8,168, out of which the directors recommend a further dividend of 2½ per cent., making the usual distribution of 5 per cent. for the year, leaving £5,668 to be carried to credit of revenue account, which now stands at £26,095.

UNDERGROUND ELECTRIC RAILWAYS CO. OF LONDON (LTD.)—The net revenue from investments and properties for half-year ended June 30 (after deducting general expenses) amounted to £106,105. 15s. The amount receivable under guarantee £2,686. 15s. 1d. The net income from the operation of the power house was £45,472. 3s. 7d., less interest, &c. (£20,870), leaving a surplus from the power house of £24,602. 3s. 7d. The bond service required £93,898. 2s. 11d., leaving a surplus over half-yearly charges of £39,496. 10s. 9d. This is to be applied in paying interest at the rate of 1½ per cent. on the 6 per cent. income bonds (£36,960. 7s. 6d.) and income tax (£2,289. 11s. 7d). Income from investments for the six months shows an increase of £15,678 (about 17 per cent.) over the same period last year. The traffics of the railway companies and the London United Tramways (Ltd.), in which this company is interested, is increasing satisfactorily. The eighth Parsons turbine has now been installed at the power house and is in operation. The net output of electric energy during the half-year was 69,636,800 units, against 63,627,200 units during the corresponding period of 1910.

NEW COMPANIES, MORTGAGES & CHARGES, &c.

NEW COMPANIES.

BERG, SHEPHERD & CO. (LTD.) (117,425)—Reg. Aug. 28, capital £1,250 in 1,000 6 per cent. preferred shares of £1 each and 5,000 deferred shares of 1s. each, to carry on the business of electrical engineers, contractors, suppliers of electricity, carriers of passengers and goods, manufacturers of electrical, railway, tramway and other apparatus, &c., to acquire the business carried on as J. Berg, and to adopt an agreement with J. Berg and F. H. Shepherd. Private company. First directors: J. Herman, C. A. Lageson, J. Berg and F. H. Shepherd.

BIRMINGHAM PRIVATE TELEPHONE (NEW SYSTEM) CO. (LTD.) (117,445)—Reg. Aug. 29, capital £2,500 in £1 shares, to carry on (so far as they lawfully can) the business of makers, sellers, maintainers and workers of private telephones, telegraphs and electrical apparatus, &c. Private company. First directors: A. Gunz (managing director and chairman) and F. T. Jackson. Reg. offices: 12, Livery-street, Birmingham.

CANADIAN POWER TRAMWAYS CONSTRUCTION SYND. (LTD.) (117,482) Reg. Aug. 31, capital £20,000 in £1 shares, to carry on the business indicated by the title. Private company. Reg. office: 6, Princes-street, London, E.C.

GROSART & KAY (LTD.) (7,976)—Reg. in Edinburgh, Aug. 28. Capital £1,000 in £1 shares, to acquire business of Grosart & Kay, electrical and engineering merchants, Glasgow. Private company. First directors: W. J. Grosart and A. E. R. Copeland. Reg. office: 196, St. Vincent-street, Glasgow.

ORIENTAL M. T. C. (LTD.) (117,469)—Reg. Aug. 30, capital £10,000 in £1 shares (4,000 preference, 4,000 ordinary and 2,000 founders), to carryion the business of financiers, concessionaires, electricians, engineers, suppliers of electricity, &c., and to adopt an agreement with the Radio & Electric Power Co. (Ltd.). Private company. First directors: W. J. Van Hoytema and A. C. Grover.

MORTGAGES AND CHARGES.

METALITE (LTD.)—Mortgage on freehold hereditaments and premises at Osmaston, Derby, and company's undertaking and property, present and future, including uncalled capital, dated Aug. 11, 1911, to secure all moneys due or to become due from the company to London, City & Midland Bank.

WARREN, BEATTIE & CO. (LTD.)—Charge on company's undertaking and property, including uncalled capital, dated Aug. 16, 1911, to secure all moneys for which the mortgagees (as guarantors) may become liable to company's bankers. Holders, Dr. D. Drummond and G. Jones. A memorandum of satisfaction in full on Aug. 16, 1911, of debentures dated May 7, 1907, and Nov. 30, 1908, securing £1,500 and £500, has also been filed.

CITY NOTES.

MEMORANDA (Sept. 7).—**Bank rate 3 per cent.** (since March 9, 1911.) **Price of silver, 24⅛d. per oz. Consols 77½—77⅝ for money; 77½—77⅝ for account. Consols Pay Day, Oct. 5; Stock and Shares Continuation Days, Sept. 12 and 25; Ticket Days, Sept. 13 and 27; Pay Days, Sept. 14 and 28; Mining Shares Carry Over Day, Sept. 11.**

PRICES OF METALS (London).—*Copper*, cash, 56; three months, 56¾. *Lead*, English, 14⅝—14¾; Foreign, cash, 14⅝—14¾; three months, 14½—14⅝. *Spelter*, 27½—27¾. *Tin*, English, 190—191; Foreign, cash, 187; three months, 185¼. *Iron*, Cleveland, cash, 46/10, three months, 47/7.

ASCOT DISTRICT GAS & ELECTRICITY CO. (LTD.)—The directors have declared an interim dividend at the rate of 5½ per cent.

BRISBANE ELECTRIC TRAMWAYS INVESTMENT CO. (LTD.)—This company's receipts for August were £24,650 (increase £2,700). Aggregate from Jan. 1, £163,520 (increase £18,725).

BRITISH ELECTRIC TRANSFORMER CO. (LTD.)—The directors have declared an interim dividend at the rate of 6 per cent. (less tax) on the ordinary shares for the past half-year.

DAVIS & TIMMINS (LTD.)—An interim dividend at the rate of 6 per cent. has been declared for the half-year to June 30.

GLOBE TELEGRAPH & TRUST CO.—The directors have declared an interim dividend of 2s. per share (tax free) on the ordinary shares for the past quarter.

HAMBURG ELECTRICITY WORKS CO.—The directors have declared a dividend of 8 per cent. for the past year.

NEWCASTLE DISTRICT ELECTRIC LIGHTING CO. (LTD.)—An interim dividend at rate of 3 per cent. has been declared for the past year.

OXFORD ELECTRIC CO. (LTD.)—The directors have declared a dividend at the rate of 6 per cent., less tax, on the ordinary shares for the half-year to June 30.

STOCK EXCHANGE NOTICES.—The Stock Exchange Committee have granted quotations to a further issue of 37,900 £1 fully-paid ordinary shares and 227,011 £1 fully-paid 7 per cent. cumulative participating preference shares of *Marconi's Wireless Telegraph Co.*

NOTES.

Universities and University Colleges.

GOVERNMENT grants are proverbially inadequate; no matter who the recipient may be, the complaint is always the same. The life of a Chancellor of the Exchequer must be a troubled one, for he is either being asked to make a grant where nothing has been given before, or to increase an existing grant. To discriminate between the worthy and the unworthy must be sometimes a difficult task, and available funds are by no means unlimited, while the prospect of the next general election is not without influence. Now, however, it would appear that Ministers are tired of being accused of parsimony and they actually turn round and complain of what is called "the apathy of the public."

A BLUE BOOK relating to British Universities and University Colleges which participate in the Government Grant was issued on Tuesday and contains an interesting introductory report signed by Mr. RUNCIMAN, Mr. TREVELYAN and Sir ROBERT MORANT. This report complains that the public do not give the financial support which they owe to these institutions; and not only is the accusation directed against the public but also against local authorities. That this is true there can be no doubt; the bulk of the people of this country take exceedingly little interest in higher education, and as to giving financial assistance, nothing is further from their minds. If it were not for a few wealthy, public-spirited individuals, our modern universities would not be in existence. The same thing is true of local authorities, who spend fabulous sums on elementary education and generally leave the rest to private enterprise.

UNFORTUNATELY, this sort of thing has a two-fold effect, for hitherto it has been the custom of the Government to intimate that the magnitude of the Parliamentary Grant is to be dependent on "local support," so that if the local support falls off so does the Parliamentary Grant. What Ministers fail to realise is that a university is an institution which renders not only local service but also national service, and that its existence should not, therefore, depend on local support. As a matter of fact, the Government itself is the chief sinner in this failure to support the universities. The total amount contributed is under £300,000 a year; there are instances, in the United States, of a single university receiving an amount equal to this from its Government. However, the report is evidence that the Board of Education, at all events, are alive to the necessity of providing larger funds, but they would rather extract them from private individuals than from the Treasury. We maintain that the State should lead the way and there would be no doubt about the public following.

Rail-less Traction at Bradford.

IT is unusual for an experimental installation to give such satisfaction from the outset as it appears the system of rail-less trolley traction at Bradford has done. In view of

Digitized by Google

the fact that this was the first time the system had been put to a practical test in this country it was anticipated that unforeseen conditions might render some modification of Continental practice necessary. This, however, does not appear to be the case, for although the installation has only been in operation some three months, Mr. C. J. SPENCER, manager of the Corporation tramways, has declared that both from an engineering and operating point of view the rail-less trolley system is an unqualified success. Moreover, not only have the Tramways Committee adopted Mr. SPENCER'S recommendations for extensions amounting to over 9 miles of route, but have added thereto a further extension of 2 miles. On account of the short length of route in operation, and of the limited experience that has so far been gained, it is rather early yet to pronounce as to the ultimate success of the rail-less trolley system, but there is no doubt that Mr. SPENCER'S report will give a fillip to electric traction in this country and provide support for those rail-less schemes which were approved by the Board of Trade in the past session of Parliament.

Electricity and Agriculture.

ALTHOUGH at the present time agriculture provides few examples of the application of electric power, it is noticeable that considerable attention is being devoted to the question, and the difficulty of obtaining manual labour is resulting in inquiries as to what can be done by the aid of electrical energy. Greater progress has been made in Germany than in most countries as regards supplying electrical power for agricultural purposes, but up to the present the results do not appear to have been very encouraging. Thus, from a note which appears in another column of this issue, it seems that the large generating stations which have been erected in Germany for supplying farms with electrical power have not so far proved a financial success. Owing to the large network which must usually be necessary to obtain an agricultural load, it is unlikely that a satisfactory return can be shown on the capital outlay in the early years of such undertakings, and it is interesting to notice that in Germany such schemes are looked to as a step towards the electrification of main railway lines.

ANOTHER direction in which important agricultural developments are likely to take place is in connection with the investigation of the effects of electricity upon the growth of plants. This, of course, does not possess such interest for the electrical engineer, since it does not promise to increase appreciably the demand for electrical energy. Important researches, however, are being carried on by a number of investigators, and it is noteworthy that two Papers on the effect of electricity upon plant life were read before the newly-formed section of Agriculture at the recent meeting of the British Association. Since the subject is of great interest to this country, and as the means at the disposal of private investigators are often limited, it is to be hoped that part of the annual grant of £50,000 which the Board of Agriculture propose in future to allocate to agricultural research will be devoted to furthering experiments on the electrification of crops.

Anglo-American—Western Union Agreement.—Yesterday (Thursday) a notice was issued to the stockholders of the Anglo-American Telegraph Co. that an extraordinary meeting will be held on Friday, Sept. 29th, for the purpose of considering and approving resolutions amending the memorandum of association of the Company in conformity with an agreement which has been entered into between the Anglo Company, of the one part, and the Western Union Telegraph Co. of the other part. The conditional agreement which has been exchanged between the Western Union Co. and the Anglo Co. provides for the purchase by the latter of the former's new trans-Atlantic cable and its equipment at a cost of about £700,000, and for the lease of the whole of the Anglo Company's cables, properties and business to the Western Union Company. A summary of the agreement accompanies the notice. The result of the confirmation by the stockholders of both companies of this agreement by the necessary majorities, and the ultimate sanction by the Court, will mean that, subject to the conditions of the lease, the Anglo Company will for 99 years be guaranteed a rent equal to dividends upon its total capital of £7,000,000 of 6 per cent. per annum on the preferred stock, 3¾ per cent. on the ordinary stock, and 1½ per cent. on the deferred stock. A circular accompanying the notice informs the stockholders that, in view of the more stringent enforcement recently in America of the Sherman Anti-Trust Act, the new agreement has been considered essential. Reference is made to the regular profits of the Western Union Company for the past ten years exceeding £1,000,000 per annum.

"Faraday House Journal."—The September issue of this periodical contains articles on "The Experimental Tank at the National Physical Laboratory"; on "The Electrification of the Randfontein Central," by Mr. T. P. E. Butt, and on a "Method of Finding the Neutral Point in C. C. Machines," by Mr. F. T. Chapman. There are besides the usual interesting news columns devoted to the doings of Faraday House and its Old Students' Association.

Thomas Alva Edison.—Mr. Edison, who has been in England for some time, is now in Vienna, and is staying at the Park Hotel, Schoenbrunn. A day or two ago Mr. Edison met an old assistant in Mr. Etienne de Fodor, general manager of the Budapest General Electric Co., who as far back as 1881 commenced pioneer work in the Edison Institute, which he continued for many years. Our good friend, Mr. Francis Jehl, informs us that the meeting of these old acquaintances was a very cordial one, and the conversation turned upon events of long ago, in which Mr. Edison and Mr. De Fodor were the principals. Mr. Edison appears to have much enjoyed his Continental trip, and expresses himself as very much refreshed. From Schoenbrunn Mr. Edison and Mr. De Fodor motored to Budapest, where Mr. Edison will be entertained.

Electric Lighting of Motor Omnibuses.—The Paris correspondent of the "Commercial Motor" states that experiments have been carried out by the Paris General Omnibus Co. with electric lighting, in place of the acetylene lamps which are at present used, on the new "single-deckers" in service in the French capital. The Company declares itself quite satisfied with the trials, and it is most probable that on the 'buses now being built electric lighting will take the place of acetylene. The apparatus used in the trials was a "Phi" dynamo supplied by the Bleriot Co.

The Practical Training of Engineers.—The "Engineer" states that a new service has been created in France during the month under the name of the French Mission of Engineers to the United States. It has been placed under the direction of M. Leclerc de Pulligny, chief engineer of the Ponts et Chaussées. The new mission is the outcome of the controversy that has been carried on for some time past concerning the value of the training given to engineers in France. No objection can be made to the theoretical and scientific character of this training although in the opinion of many it is carried to an extreme, and if combined with practical instruction there is no doubt that the result would be highly satisfactory. As it is, engineers leaving the different *écoles* are often totally lacking in prac-

Digitized by Google

tical knowledge, and have some difficulty in acquiring the experience necessary to succeed in their profession. As far back as 1908 the matter was brought up in the Chamber of Deputies, when the Government was invited to send a certain number of engineers from the Ecole des Ponts et Chaussées to complete their training in the United States. The idea is now being put into effect by the Minister of Public Works, who has decided upon sending engineers from the Ecole des Ponts et Chaussées to the United States, where they will be employed for a period of at least two years in the public works departments, or by the railway companies or big industrial concerns. After completing this practical training they will be required to take up service with the State for a minimum period of 10 years. M. Leclerc de Pulligny is on the point of leaving for New York, where he will take up his residence and organise the new service. It is believed in France that the experience gained on the other side of the water will considerably raise the standard of engineers, who, in the opinion of the heads of some big industrial undertakings, have been steadily declining in value for some years past on account of the purely theoretical character of the instruction given them.

Electrodes for Electric Furnaces.—The "Electrical World" states that two patents relating to electric furnaces were issued to Mr. Carl Hering on August 1st. Of these one covers electric furnace electrodes so designed as to afford the greatest economy in material and the least loss in electrical energy. The invention is based on deductions from the laws of electrode losses discovered by the inventor some years ago and described by him at that time in various Papers and articles. Briefly, the fundamental principle is as follows: An electrode should be a good electrical conductor to reduce the loss of energy due to electrical resistance; on the other hand, good electrical conductors are as a rule also good heat conductors; they thus tend to conduct heat away from the inside of the furnace where the heat is wanted. Increasing the cross-section reduces the former loss, but increases the latter, while increasing the length does the reverse. The problem therefore is to find the conditions under which the total combined losses are least. This the inventor found is the case when the length and section are so proportioned that the current heats the electrode sufficiently to raise the inner or hot end to the furnace temperature. Under these conditions no heat will be abstracted by the electrodes from the charge in the furnace, and the entire loss of heat energy will thus be only that portion generated in the electrodes. This, moreover, is the condition under which the total loss of energy will be the least possible, for under any other conditions the total combined losses will be greater and the electrodes will either chill the furnace product or will develop excessive heat where they pass through the walls. These same laws also lead to economy of the materials of the electrodes, thus reducing their cost. Determinations of physical constants in the application of these laws showed the surprising fact that copper is the best material for electrodes, iron is nearly as good, and that gas carbon, which was the most generally used electrode material, is the worst, graphite being decidedly better than carbon. In general, the results showed that metal electrodes are cheaper and more economical in energy and should therefore be employed whenever it is possible to use them. The other patent of the same date is for furnaces whose electrodes are designed and proportioned in this way; that is, for combinations of such electrodes with furnaces, more especially with furnaces in which the electrodes are not consumed, as in the one recently devised by the same inventor. When such electrodes are virtually prolongations of the resistances and are of the same material they automatically adjust their length so that the proportions will remain practically correct for different temperatures and currents.

Improvements in Magnetic and Electrostatic Separators.—According to the "Engineering and Mining Journal," one of the principal defects in the ordinary electromagnetic or electrostatic separator arises from mechanical interference between the particles of ore, due partly to incomplete screening before concentration, and partly, also, to the fact that when mixed particles are allowed to pass under the influence of the lines of force in the magnetic field, the magnetic particles coalesce into a mass which will generally include and prevent the removal of non-magnetic particles. As a means of overcoming this defect when due to the latter cause, Mr. Q. Payne, of New York, has patented an improved type of drum to be used in connection with either an electromagnetic or an electrostatic separator. The drum is composed of a series of metal discs, iron or steel in the case of a magnetic separator, and brass, aluminium or any other metal, in the case of an electrostatic separator. These discs are mounted on a shaft and are insulated from one another by corresponding discs of some non-conducting material, like fibre, mica, &c. The object of the discs is to prevent the accumulation of masses of metal particles, in which non-metallic particles will be embedded. Theoretically, the best results would be secured if the discs were of the same thickness as the grains of ore to be treated, but, practically, it is found that sufficiently good results are secured if the discs do not exceed three or four times the diameter of the grains.

Current Topics.

Subjects of current interest dealt with in this issue include the following:—

Dr. R. A. Houstoun continues his series of articles on "Studies in Light Production," considering this week "The Black Body."

Dr. J. R. Ashworth contributes an article on "A Simple Graphical Method for the Harmonic Analysis of a Cyclic Function."

We give abstracts of the following Papers read at the recent meeting of the British Association: "Electrical Steering," by Mr. B. P. Haigh; "Some Preliminary Notes on a Study as to Human Susceptibility to Vibration," by Mr. W. Pollard Digby and Capt. H. Riall Sankey; "The Manufacture of Nitrogen Compounds by Electric Power," by Mr. E. Kilburn Scott; "Continuous versus Intermittent Service in Passenger Transportation," by W. Y. Lewis; "Suction Gas Engines and Producers," by Mr. W. A. Tookey; "The Electrical Conductivity of Light Aluminium Alloys," by Prof. E. Wilson.

At the Annual Convention of the American Institute of Electrical Engineers Major G. O. Squier read a Paper on "Multiplex Telephony and Telegraphy by Means of Electric Waves guided by Wires."

We analyse the accounts of the West Ham electric supply department for the year ended March 31, 1911.

Bradford Tramways Committee recommend the equipment of about 11 miles of route on the rail-less trolley system. It is reported that the experimental line has proved an unqualified success.

OBITUARY.

W. Hey.—We regret to record the death of Mr. Wm. Hey, who for many years was head foreman in the dynamo shops at the Halifax and Woodfield works of Messrs. W. T. Goolden & Co., and who afterwards held the same position with Messrs. Greenwood & Batley at Leeds. Although of a strong personality, the deceased had a most affectionate nature, and was extremely popular with the large number of pupils who passed through his hands, as well as with the staff and the men who worked under him. The news of his death will doubtless be learnt with regret by many old "Goolden" men.

E. Stiff.—We also regret to record the death on the 6th inst., at Eastbourne, of Mr. Ebenezer Stiff, of Lambeth and Wimbledon. Deceased, who was 71 years of age, had been a member of Messrs. Jas. Stiff & Sons.

APPOINTMENTS VACANT AND FILLED.

An analytical chemist is required for a cable factory. Preference will be given to one having electrical knowledge. See an advertisement.

Digitized by Google

An assistant superintendent of railway telegraphs is required by the Government of Southern Nigeria for one tour of 12 months' residential service, with possible extension. Salary £250, rising to £300 per year by annual increments of £10. Applications by letter to the Crown Agents for the Colonies, Whitehall Gardens, London, S.W. See also an advertisement.

Swindon Corporation require an assistant electrical and mechanical engineer for their electricity and tramways departments. Salary £130, rising to £180. Applications to the Town Clerk by Sept. 23.

Mr. T. Harris, B.A., B.Sc., has been appointed assistant lecturer and demonstrator in the physics department of East London College.

Mr. D. M. Dunlop has been appointed secretary of the National Electrical Manufacturers' Association.

Mr. W. J. Carter, of Oldham, has been appointed assistant electrical engineer at Batley at a commencing salary of £130 a year.

Mr. Chas. T. Cole has been appointed mains assistant at Devonport.

Dewsbury Council have appointed Mr. S. H. Fowles as an assistant in the mains department.

INSTITUTIONS AND SOCIETIES.

British Association.—The following is a list of the Papers and reports dealt with by the Engineering Section of this Association during the recent meeting at Portsmouth. Presidential Address, by Prof. J. H. Biles; "The Anschutz Gyro-Compass," by Mr. G. K. B. Elphinstone; "Electrical Drives for Screw Propellers," by Mr. H. A. Mavor; "Electrical Steering," by Mr. B. P. Haigh; "The Single-Phase Repulsion Motor," by Mr. T. F. Wall; "Some Preliminary Notes on a Study as to Human Susceptibility to Vibration," by Mr. W. Pollard Digby and Capt. H. Riall Sankey, R.E.; "The Electrical Conductivity of Light Aluminium Alloys," by Prof. E. Wilson; "Recent Developments in Radio-Telegraphy," by Prof. G. W. O. Howe; "Portable Equipment for Wireless Telegraphy," by Capt. H. Riall Sankey, R.E.; "Economical and Reliable Power Generation by Over-type Superheated Steam Engines," by Mr. W. J. Marshall; "Suction Gas Engines and Producers," by Mr. W. A. Tookey; "Crude Oil Marine Engines," by Mr. J. H. Rosenthal; "The Manufacture of Nitrogen Compounds by Electric Power," by Mr. E. K. Scott; "Smoke Abatement," by Dr. J. S. Owens; "A New System of Continuous Transportation," by Mr. W. Y. Lewis; Report of the Committee on Gaseous Explosions and a joint discussion with Section A on "Aeronautics." The following matters of electrical interest were dealt with by Section A: "The Infinitesimal Transformation of an Electromagnetic Field into Itself," by Mr. H. Bateman; "A Friction Permeameter," by Mr. W. H. Murdoch; "The Work done at the Bureau of Standards on the Absolute Measurements of Electric Current," by Prof. N. E. Dorsey; "The Specific Heats at High Temperature and the Latent Heats of Metals. Part I.: Aluminium and Zinc," by Mr. H. C. Greenwood; and the Report of the Committee on Experiments for Improving the Construction of Practical Standards for Electrical Measurements. In Section B a Paper on "The Present Position of Electric Steel Making" was read by Prof. A. McWilliam, and a report on "Electro-analysis" was also presented.

Tramways and Light Railways Association.—The "Journal" for September of this Association contains the following matters: The recently published Board of Trade Regulations with respect to the use of electrical power by tramways; the official report on the accident at Stalybridge on June 5, 1911; correspondence in regard to Tramway Fares; a copy of the "Special Case" stated for the King's Bench Division *in re* "Metropolitan Electric Tramways v. Tottenham U.D.C."; a reprint of a Paper on "Tramcar Meters, &c." read by Mr. A. Sharman Giles before the Institution of Civil Engineers, and other matters relating to the Association.

International Congress for the Applications of Electricity, Turin.—At the opening meeting of this Congress on Sunday, Sept. 10, the following were among those appointed to offices in connection with the Electrical Congress now in session at Turin:—As Vice-Presidents of the Congress: Mr. Alexander Siemens and Dr. S. P. Thompson, F.R.S.; as President of the Section of Telegraphy and Telephony: Major W. A. J. O'Meara, C.M.G.; as Vice-President of the Section for Accumulators and Electro-chemistry: Mr. W. Duddell, F.R.S.

Association of Mining Electrical Engineers (West of Scotland Branch).—The local Council of this branch have just submitted their first annual report, in which they mention that the branch was successfully inaugurated on Sept. 17, 1910, at a public meeting in Glasgow, and eight meetings have since been held in the Glasgow Technical College, by the kind permission of the Governors. There were also two very successful joint meetings with the National Association of Colliery Managers. The first was held in Edinburgh, when Mr. H. W. Clothier gave a very interesting account of the progress made in "Switchgear" from the earliest known to recent types, suitably illustrated by numerous lantern slides; and the second in Glasgow, when Mr. R. Nelson, H.M. Electrical Inspector of Mines, gave a very interesting Paper on "The Avoidance of Electrical Accidents in Mines," to an audience numbering close on 500. Papers read at the other branches throughout the Kingdom have also been freely discussed. The branch has been particularly fortunate in the matter of Papers during the past session, as evinced by their widespread interest, but it is felt that sufficient use is not being made of the Association in another direction, namely, in the matter of questions and answers. It is sufficient for a member to submit a query, under a *nom de plume* if he prefers it, at any of the public meetings, and obtain enlightenment or a discussion on the point in doubt. The first examinations for admission were held throughout the country during March last, when 75 members sat. Of these 32 gained first class passes, 25 second class and 6 service certificates. Although the percentage of candidates from Scotland was small, possibly the addition of the branch president to the examination board, on which the branch is to be congratulated, may in the future mend this feature. The branch is also to be congratulated on having had the services of Prof. Burns as local examiner. It is appropriate that the General Council should thus early in the life of the Association accept the invitation of this branch to hold the annual meeting in Glasgow, the district possessing the first colliery in the world to make use of electricity in any form. Since the acceptance of the invitation the branch Council, along with representatives from the East of Scotland Branch, have been assiduous in drawing up an attractive programme, and it is earnestly hoped every member of the branch will do his utmost to attend personally. The programme covers two days, viz., October 6 and 7. As regards the coming session, the local Council make the suggestion that interesting Papers can be written on the following subjects, but do not suggest they be confined to any or all named:—"Speed Reduction, so far as it relates to Electric Motor Driving"; "Cable Systems and Earthing"; "Relative Advantages of A.C. and D.C. Systems for Small Collieries"; "Systems of Lighting from Power Mains, especially with regard to Personal Safety Underground"; "The Standardisation of Colliery Electrical Equipment to the recommendations of the Engineering Standards Committee"; "Methods of installing Shaft Cables"; "Leakage Protection Devices of proved efficiency." It is advisable and will avoid overlapping if the hon. secretary is early acquainted with the intentions of any member in this connection. It may interest local members to know that there are numerous premiums offered for excellence in Papers read before the Association, and that a £5 premium has been recommended to be awarded to Mr. Thomas Thomson, a member of this branch, for his Paper last session. It is the intention of the local Council to hold additional meetings at various centres in the area, such as Larbert, Hamilton, Kilmarnock, &c., but the details are not yet sufficiently advanced for a programme to be embodied with this report. The idea is to broaden the basis of the organisation, increase its usefulness, and incidentally to increase the membership. The number of members on the branch at present is 125, a matter for congratulation, considering it is the first session. It is felt, however, that in such a district as the west of Scotland, where there are over 300 collieries, the number of members can be considerably increased with mutual benefit to all concerned. Members will greatly assist the local Council in considering the claims of special districts for these lectures if they will submit the names of localities where they think it would be advantageous to hold a special meeting. In doing so they should be prepared to co-operate with the Council to ensure the success of a meeting

Institute of Metals.—The autumn meeting of this Institute will be held at Newcastle-on-Tyne on September 20, 21 and 22. The members will be entertained by the Lord Mayor, and visits will be paid to certain works of metallurgical interest in the neighbourhood. The following Papers, among others, will be read: "The Corrosion of Brass with Special Reference to Condenser Tubes," by Mr. P. T. Brühl; "The Electrical Conductivity and Constitution of Alloys," by Dr. W. M. Guertler; "Non-Ferrous Metals in Railway Work," by Mr. G. Hughes; and "The Mechanical Properties of Hard Drawn Copper," by Mr. D. R. Pye.

Digitized by Google

EDUCATIONAL NOTICES.

University of London, University College.—The new session commences on Monday, Oct. 2. There are complete courses of study, extending over three years, in mechanical, electrical, civil and municipal engineering. Intending students should communicate with the Provost as soon as possible, and full particulars may be obtained on application to the secretary, Mr. Walter W. Seton, M.A., Gower-street, W.C.

University of London, King's College.—Complete courses of study, extending over three or four years, are provided by this college in civil, mechanical and electrical engineering for engineering degrees of the University of London, and for the diploma and certificate of the college. The four years' course provides, in addition to the academic training, opportunity for practical training in works. Full information may be obtained from the Dean or the Secretary, King's College, Strand, London, W.C.

University of Manchester.—In the faculty of science complete courses of study extending over three years are arranged for the University degrees in civil, mechanical and electrical engineering. The session commences on Oct. 2.

University of Edinburgh.—The next session opens on Oct. 10. The University provides complete courses in civil, mechanical and electrical engineering, qualifying for the degree of B.Sc. in engineering, and extending over a period of three years. Particulars of the entrance examination, scholarships, fees, &c., can be obtained from the Matriculation Office, The University, Edinburgh.

University of Bristol.—The session in the faculty of engineering commences Sept. 15 and in faculties of arts, science and medicine on Oct. 2.

The faculty of engineering of this university is provided and maintained in the Merchant Venturers' Technical College. There are courses in civil, mechanical, electrical and motor-car engineering. The Dean of the Faculty is Prof. J. Wertheimer, B.Sc., B.A. Copies of calendar or prospectus may be obtained from the Registrar.

The Proctor-Baker scholarship, tenable by a pupil of the Merchant Venturers' Secondary School in the faculty of engineering of the university has been awarded to Mr. John Rogers.

University of Durham.—Armstrong College, Newcastle-upon-Tyne.—The 1911-12 session commences Sept. 25. There are departments of mechanical, marine, civil and electrical engineering, naval architecture, mining, metallurgy, agriculture, pure science, arts and letters. Particulars may be obtained from the secretary, Mr. F. H. Pruen, M.A.

Goldsmith's College (University of London).—At this college complete evening courses of instruction are provided in mechanical, electrical and constructional engineering, land surveying, fitting and machining, pattern-making and smithing. Students are prepared for the London University degree of B.Sc. in engineering, for the examinations of the Institution of Civil Engineers, Board of Education, and City and Guilds of London Institute, &c. Particulars from the Warden of the College, New Cross, S.E. The new session commences on Monday, Sept. 25, and enrolling will begin on the 18th inst.

University College of North Wales.—At this college a systematic course of instruction in electrical measurements and practical electricity is provided for students proposing to enter the electrical engineering profession. The physical laboratory is well equipped for practical work and the fee for the ordinary course is £17. 1s. per session. The next session commences in October.

Northampton Polytechnic Institute, Clerkenwell, London.—The full day courses in the theory and practice of mechanical and electrical engineering and in electro-chemistry will commence on Oct. 2, and entrance examinations will take place on Sept. 27 and 28, at which five entrance scholarships will be offered. The courses for mechanical and electrical engineering include periods spent in commercial workshops, and extend over four years, and they also prepare for the degree of B.Sc. in engineering of the University of London. There are also full and partial day courses in technical optics. Particulars from the Principal, Dr. R. Mullineux Walmsley.

Borough Polytechnic Institute.—A four years' course of instruction in electrotechnics is provided at this Institute. There are also classes in electric wiremen's work, and elementary and advanced courses in electrical design and workshop drawing. The head of the department is Mr. John Henderson, D.Sc., F.R.S.E., A.M.I.E.E. Prospectuses, containing further particulars and detailed syllabus, from the Principal, Mr. C. T. Millis, Borough-road, S.E. The session begins on 25th inst.

Battersea Polytechnic (London, S.W.).—The new session commences on Monday, 25th inst. There are complete day college courses in civil, mechanical and electrical engineering, extending over three or four years. These courses are suitable for preparing for the B.Sc. (Eng.) of the University of London, the Associateship examination of the Institution of Civil Engineers, &c. There are also evening classes in electrical technology, electrical design and power distribution, theory of machines, hydraulics, heat engines, strength of materials, &c. Further particulars can be obtained from the Secretary.

A course of 12 lectures, six during the first term and six after Christmas, will be given on "Illuminating Engineering." On Oct. 17 and 24 Prof. J. T. Morris will lecture on "Electric Lighting;" on Oct. 31 and Nov. 7. Mr. J. G. Clarke will lecture on "Gas Lighting." Mr. E. Scott Snell will deal with "Oil, Petrol-air and Acetylene Gas" on Nov. 14, and Dr. W. J. Ettles will give a lecture on "Illumination and the Eye" on Nov. 21. The remaining six lectures (to be delivered in the second term) will deal with the Measurement of Light and Practical Problems in Illumination and will be delivered by Mr. J. S. Dow, B.Sc., The fee for the full course is 7s. 6d. Further particulars from the Secretary.

The calendar for the new session, which opens on Sept. 25, gives full details of the numerous courses and classes. Full day and evening courses in preparation for the Intermediate and Final Degree examinations in science, engineering and music are offered, and the lecturers in the various subjects are fully recognised by the University of London, so that students attending the Polytechnic may be registered as internal students of that University. In the Day Technical College, full time courses are arranged in mechanical, civil, electrical and motor engineering, architecture and building, chemical engineering and art, the courses covering a period of 3 years, at the end of which time students passing the necessary examinations are awarded the Polytechnic diploma. Concurrently with the diploma courses, students can prepare for and take the degree courses in science and engineering of the University of London. The Commerce department gives a course extending over two or three years in preparation for civil service and other examinations and for secretarial and other business appointments. In addition to the scholarships already existing, the governing body have instituted one of £40 a year for three years tenable at the Day Technical College. It is believed that this scholarship will fill a direct want by providing a scholarship which not only entitles to free fees, but gives a sum of money to help towards maintenance. Full and complete evening courses are provided in the departments of mechanical engineering and building trades, electrical engineering, mathematics, physics, chemistry, natural science, languages, commerce, &c. In the mechanical engineering department a course of lectures on illuminating engineering has been arranged, and should the course prove successful it will be amplified and continued during succeeding sessions.

In the electrical engineering department special attention is being given to the subject of electric traction, and new machinery and apparatus are being purchased in order that the subject may be more fully and thoroughly dealt with. In the physics department, the course on acoustics for music students will be repeated, and a class in physical chemistry for chemistry students has been arranged. In the chemistry department, the chemical engineering course has been extended by the addition of a practical class.

It may be also stated that the Edwin Tate Library, which was opened last October by the Archbishop of Canterbury, has fully justified its erection, and has proved a great boon to students, the number of books borrowed having increased nearly 50 per cent. during the session. With the many valuable additions to the books there is now available for the use of students a really first-rate library housed in a building of which the Polytechnic may justly be proud.

East London College (University of London).—In the Faculty of Engineering complete courses of instruction are provided in engineering subjects, including civil, mechanical and electrical engineering. There are special facilities for apprentices on the sandwich system. The fee for the session is 10 guineas. Further particulars from the Registrar or from the principal, Mr. J. L. S. Hatton, M.A.

L.C.C. School of Building.—Up till recently no adequate course of instruction was available for students of reinforced concrete, but last winter the deficiency was repaired by the establishment of classes in this subject at the L.C.C. School of Building, Ferndale-road, Brixton, S.W., the lecturer being Mr. H. Kempton Dyson, secretary of the Concrete Institute. As the result of the experience last session the scheme of instruction has been further extended, and the scope enlarged for next session which commences on 18th inst. This year many more testing appliances, tools, &c., have been added, and a more systematised courses of instruction will be possible. Detailed syllabus can be obtained free at the school.

ARRANGEMENTS FOR THE WEEK.

THE LONDON ELECTRICAL ENGINEERS.

Officer Commanding, Col. H. M. Leaf.

The following orders have been issued :—

Head-quarters will be closed for instruction, but will be open for office work as under until further orders :—

Monday to Friday, 10 a.m. to 4 p.m.

Saturday, 10 a.m. to 12 noon.

Digitized by Google

ELECTRICAL STEERING.*

BY B. PARKER HAIGH, B.SC.

Summary.—The author describes the two different ways in which the electric drive may be applied to the average steering gear and the questions of design that have to be solved in so applying it. Motors for this purpose need not be designed to carry their full power continuously. Details as to power requirements and of actual gears are also given.

To many who are familiar with the development and the present reliability of steam steering engines, it must appear doubtful whether electrical power can offer any considerable advantage for this purpose. The steering gear being one of several important auxiliaries carried by the ship, the question involves the power supply for all of these. It is generally admitted that the present system of supplying auxiliaries with steam is not only inconvenient but wasteful in the extreme, partly on account of the low economy of small engines worked non-expansively, and partly on account of leakage and condensation in the steam mains. A number of vessels have been equipped with partial installations of electrical power, in some cases for the cranes and boat hoists, in other cases for fans, and as the difficulties connected with these have now been largely overcome a considerably extended use may be expected.

It is beyond the scope of this Paper to deal with the use of electrical power for auxiliaries in general, but it is desired to emphasise the disadvantages of a mixed power system involving the upkeep charges on both steam mains and electrical installation. Vessels fitted with internal-combustion engines offer a special field for electrical steering; for on such vessels the steam supply, if available at all, would not generally be maintained at sea.

Electrical power may be applied in steering in connection with two separate problems. In the first place, electrical apparatus may be used in place of the customary control shafting or hydraulic telemotor to transmit the motion of the hand wheel aft to the steering engine. Several such electrical "telemotors" are now available, and these have the advantages of being very easily worked, even in the longest ships, and of convenience in installation. The second problem is that of supplying and controlling electrical power for moving the rudder itself, and it is here that electrical steering offers the greater advantage over gears now in general use requiring a supply of steam. The main difficulties experienced in electrical steering have been those of limiting the amount of power required to the capacity of the ship's dynamos, and in controlling the heavy power in a reliable manner. The electric motor must not only be arranged to move the rudder promptly and accurately within the small angles of 5 deg. or less that are required for keeping a course, but must also be capable, without any adjustment of the control gear, of rapidly putting the helm hard over, 35 deg. to either side, against heavy water resistance. As this is the crux of the whole question, it may be well to state working conditions in some detail.

The action of a rudder in steering is similar to that of the blades of an "Impulse" turbine. Water flowing under the counter of the vessel strikes the rudder surface and is deflected so that its subsequent motion is more or less parallel to the direction of helm. In changing its direction of motion the water exerts a certain force on the rudder, tending to swing the vessel about an axis somewhere well forward in its length, and also acting as a drag, reducing the speed of the vessel. The steering moment reaches a maximum when the angle of helm is about 40 deg., and as the drag increases quickly it is not customary to arrange the steering gear for angles of over 35 deg. The time generally taken to bring the rudder from hard-over port to hard-over starboard, or vice versa, varies from 15 seconds or even less in small vessels, to about 40 seconds in the largest, these times being those required while under way ahead.

The power required in the steering engine depends upon the torque produced in the rudder post by the water pressure, which is usually of considerable magnitude, as the centre of water pressure is generally some distance abaft the axis of the rudder post, even when a "balanced" rudder is used. Little effort is required to move the rudder within small angles, even when an "unbalanced" rudder is used, partly because the angle of deflection of the water is small and partly because the centre of pressure on the rudder surface is near the leading edge. Unless a heavy sea strikes the rudder, the steering motor has, therefore, little to do beyond overcoming friction within the gear itself; and as the great majority of steering motions consist in moving the rudder through small angles near the midships position it will be recognised that electrical power promises economy as compared with either steam or hydraulic power. When the angle of helm is increased, the torque in the rudder post increases rather more rapidly than the sine of the angle, for an increasing body of water is deflected and the centre of pressure shifts further from the leading edge of the rudder surface. After the rudder has been held hard-over for a few seconds the torque in the rudder post falls off somewhat, partly because the vessel commences to swing and partly because the vessel's speed is reduced, but it is clear that the steering gear must be designed to meet the heavier initial stresses and it is fortunate that these can be readily estimated.

In order to economise power the gearing between the electric motor and rudder post should be designed for a high efficiency, and consequently it will not be "self-sustaining." Means must therefore be provided to hold the rudder in its hard-over position. A magnetic brake similar to those used on cranes is suitable for this purpose and will also serve to stop the gearing promptly when the required position has been reached. In returning the rudder to the midships position while the vessel is moving ahead, the force of the water assists the motion of the rudder, and this complicates the matter of the control. Further, when the flow of water past the rudder is reversed, by reversing the propellers, the centre of pressure shifts towards the after edge of the rudder surface and considerable power is then required to bring the rudder back amidships even when the speed of the ship is low. It is this fact which prevents a rudder being balanced under all conditions, but nevertheless balancing is a great advantage for electrical steering, allowing a smaller motor to be used, minimising the demand for current and reducing the wear and tear on the control gear.

Experience has led to the design of steam engines of special proportions for steering, and in the same way electrical motors used

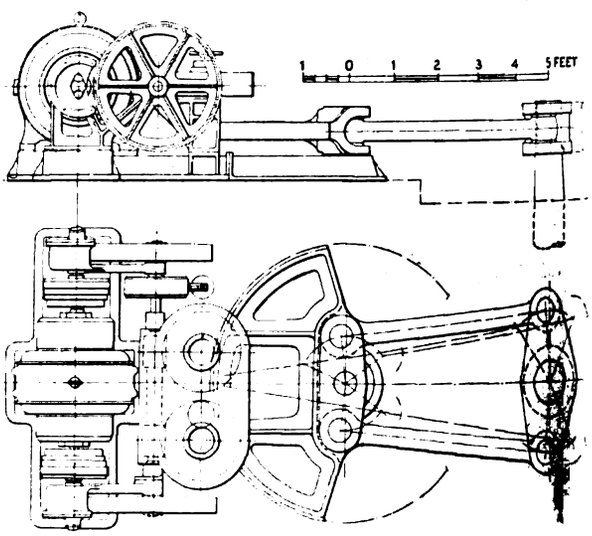

FIG. 1.—ARRANGEMENT OF ELECTRICAL STEERING GEAR FOR 11½ IN. RUDDER POST.

need not be designed to carry their full load continuously. Motors of smaller dimensions, for "half-hour rating" and fitted with commutating poles are preferable, and as the heating limit is not here in question the motor may be totally enclosed even in large sizes, without any considerable increase in its dimensions.

Besides possessing adequate power, a steering gear must be satisfactory as regards sensitiveness, that is, it must be capable of moving the rudder to an angle that accurately corresponds to the position of the steering wheel. This is especially necessary within the range of small angles that are used for keeping the vessel on its course. In any steering gear there is naturally some "idle travel" of the steering wheel within which the gear will not respond. In long ships this is minimised by using a telemotor in place of control shafting with gearing, in which latter the total effect of spring and back-lash may be objectionable. But apart from such loss of motion there is a further idle travel due to the practical necessities of the control valve or control switchgear, and this loss is kept as low as possible. Requirements as regards sensitiveness vary greatly and high-speed vessels naturally require closer control than slower vessels, for as the size of the rudder cannot be reduced without loss of manœuvring power at low speeds, very small angles of helm are sufficient for ordinary steering. In the highest class work the steering gear should respond to a motion of the hand wheel corresponding to one degree of helm (less than one-eighth turn of the wheel). Little advantage is gained by working closer than this, and many high-speed vessels with fine lines are worked with gears requiring double this allowance. A certain small amount of idle travel is desirable to prevent the gear

* Paper read before Section G (Engineering) of the British Association at Portsmouth.

Digitized by Google

being used too frequently. Sensitiveness does not only depend on the idle travel of the wheel but also on the "time lag," i.e., the interval between the movement of the wheel and the corresponding movement of the rudder. In this respect it appears that electrical steering may possess considerable advantage over ordinary steam gears, for as it can be arranged that the rudder responds more quickly a closer course may be kept with watchful steering. As regards idle travel there is little to choose between steam or electric gears. In steam gears the idle travel is kept down by reducing the already small steam lap on the control valve, which, in order to obtain a fast-running gear with little time lag, is generally a piston valve of ample size. Such a valve is liable to leakage when slightly worn. In electrical gears, on the other hand, sensitiveness does not reduce the economy but complicates the control arrangements.

In the following table a number of different types of electrical steering gear are classified according to the method of control :—

A. Steering gears in which the motor is started and stopped for every motion of the rudder.

(1) The motor being supplied with current at variable voltage from a special generator.

(2) The motor being controlled by reversing switch and resistances.

B. Steering gears in which the motor is kept running continuously ; mechanical control being introduced in one of the following forms :

(1) Friction clutches with gearing.

(2) Hydraulic transmission with rotary or reciprocating pumps.

(3) Magnetic friction clutches on motor shaft.

The second line of development, including the gears grouped together under heading B, appears to offer more promising results than method A, to which one great objection is the wear and tear unavoidable where so much switchgear for heavy currents is used. A further advantage of the different types classed together under B is that the shock of the sea on the rudder is greatly reduced before it reaches the ship's electrical installation. The armature of the motor acts as a flywheel, or extra flywheel weight may be added, and by using a compound motor a large part of the energy kinetically stored in the revolving masses is given up to the steering gear before any excessive current is demanded from the ship's mains. The steering gear can therefore be supplied from the ship's lighting generator without any noticeable flicker in the lamps coupled to the same mains. It is difficult to overestimate the importance of this feature, both as regards simplicity, and consequently reliability, and as regards economy of power.

To indicate the amount of power required under these conditions we may take the case of the proposed gear described later, and shown in Figs. 1 and 2. This is designed for an 11½ in. rudder post, suitable for a vessel of, say, 450 ft. in length, of 16 knots speed. In this case a motor of 30 B.H.P. is provided, capable of developing a torque of 175 ft. tons in the rudder post, and of moving the rudder through 70 deg. in 20 seconds. These figures are based on special features in the design of the gear and on an efficiency of 64 per cent. in the gearing, which, though high in comparison with that of gears having right and left-hand screws, is not higher than that obtainable with double-worm drive. The 30 H.P. motor would be a continuous-current motor with compound winding, and would run at a speed of 500 revs. per min. under full load, and at varying speeds up to 1,000 revs. per min. on lighter loads. The current required at full load would be 270 amperes at 100 volts. In some respects, and especially as regards reliability, a three-phase motor is preferable to the continuous-current motor, but its constant speed characteristic causes a heavier maximum demand for power. The choice of the type of motor to be used on any particular vessel naturally depends on many matters outside the steering gear. A vessel of this size, engaged in passenger service, would probably be provided with generating plant for lighting and forced-draught purposes of about 200 kw. and if this is divided among four dynamos, each of 500 amperes capacity at 100 volts, it should be possible for any one of these running alone to put the helm hard-over in emergency.

Probably the first electrical steering gear in which the motor was kept running continuously was that designed and built in 1895 by the late Mr. A. B. Brown, who may be justly regarded as the pioneer in the scientific development of power-steering gear. Being constructed on the same principle as his well-known steam tiller, the motor of this gear was mounted on a forged steel tiller which carried a pinion engaging with a toothed rack attached to the deck. The control was by means of two metal to metal friction clutches with coil springs, driven at a lower speed than the motor by means of gearing. The clutches were arranged to move the tiller in opposite directions and the chief difficulty experienced was that of obtaining accurate and sensitive control.

In the steering gear designed by the writer in conjunction with Messrs. Brown Bros. & Co., of Rosebank, Edinburgh, the control is by means of magnetic friction clutches, which have several advantages due to the absence of external thrust and the ease of the control. A number of tests have been made on an experimental gear of fair size and it is hoped that some particulars may be of interest. Figs. 1 and 2 show details of a proposed gear suitable for an 11½ in. rudder post, to which reference has already been made in connection with the amount of power provided. Although the motor in this gear runs continuously, no gearing is kept in motion as the motor shaft is extended at either end to carry the two magnetic clutches, which are normally out of gear, leaving the rudder stationary. The driven portions of these clutches are carried on bearings and are geared to the countershaft carrying the worm gear in such a way that the rudder is moved to either port or starboard by bringing one or other of the clutches into action. The two parts of the clutch are drawn together by magnetic attraction and a light spring is provided for withdrawing the clutch after the motion required is completed. The friction drive is transmitted by red fibre blocks bearing on the conical edge of the light steel disc that acts as the keeper of the magnet, and no thrust remains to be taken up by collars. Either ball bearings as shown in Fig. 2 or ring oiling journals may be used, provided the motor has not excessive end play. Provision is made for taking up wear on the fibre blocks by adjusting the inner ring on the clutch body to feed the blocks through holes in the outer ring. In the gear suitable for an 11½ in. rudder post, the clutch coils are fed with a current of ½ ampere, supplied through slip-rings enclosed within the motor. No electrical parts are therefore exposed to the action of damp, for as the motor is always running, it keeps itself dry. Should it be de

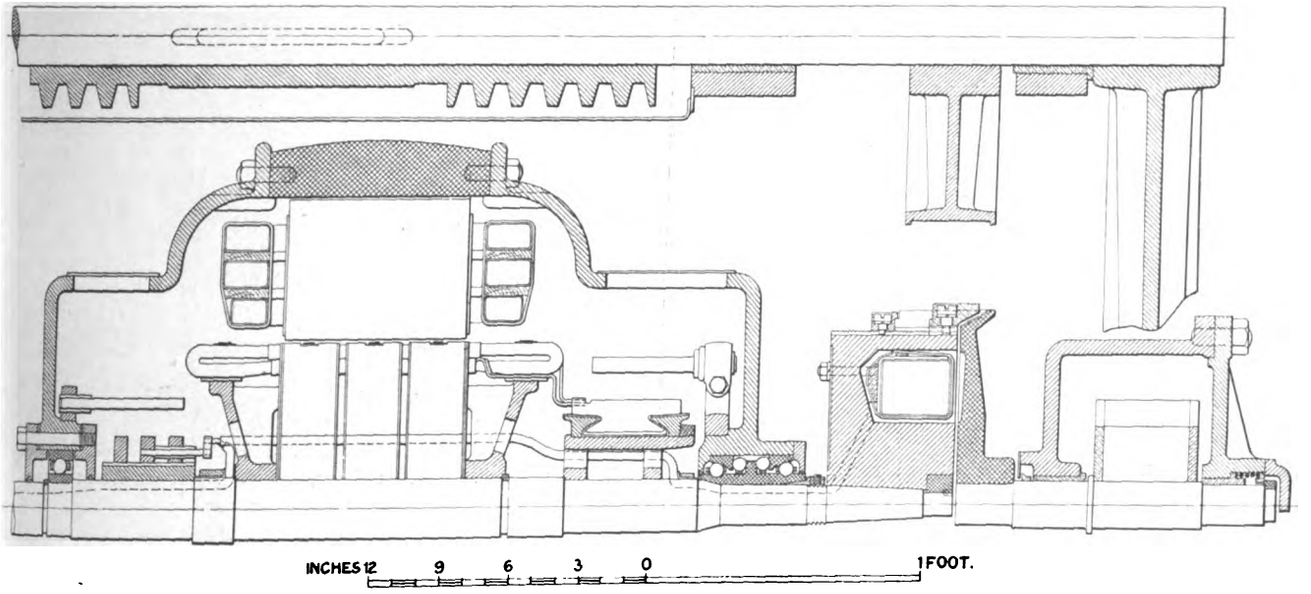

FIG. 2.—MOTOR, CLUTCH AND GEARING FOR STEERING GEAR FOR 11½ IN. RUDDER POST.

Digitized by Google

sired to remove the armature, the clutches are removed at the same time, after sliding the fibre friction blocks back by turning both screwed rings on the clutch body. Impregnated fibre friction blocks have the advantage of engaging silently, whereas wood, although in some cases having a higher coefficient of friction, appears liable to squeak painfully. The mechanical arrangement of the gear, shown in Fig. 1, has certain novel features, notably the use of two pinions engaging with the toothed sector. As these carry equal loads the wear is distributed, and a lighter sector may be used, with teeth of reduced pitch as compared with those necessary if only one pinion were provided. Further, a lower ratio of worm gear is required and a higher efficiency obtained. The loads on the two pinions are kept equal by using right and left-hand worm-gear with an intermediate pinion to keep the directions of rotation right. The two worms are cut on a sleeve sliding freely on the shaft without thrust blocks, and as a certain amount of end play is provided between the bearings, the teeth of the sector can be allowed a considerable amount of wear without disturbing the equal distribution of the load. The quick pitch of the worms and the absence of frictional loss at thrust blocks ensures a very high efficiency being obtained.

The power required is further reduced by the use of variable leverage linkwork, in which the rudder crosshead and the dummy crosshead carrying the toothed sector are connected together at different radii so that the connecting rods do not form a parallel motion. The leverage, which in the midships position is 1·5 to 1, increases gradually to 2·2 at the hard-over position of 35 deg., so that the maximum torque is obtained with less current when the rudder is hard-over; and, further, the gear responds more quickly in the ordinary working range amidships. As this linkwork is not a so-called "geometrical" motion the position of the crosshead pins must be carefully chosen, and when this is properly done no difficulty is found in working over to 38 deg. of helm. In this way a saving of 30 per cent. can be made in the motive power, and taking account of the extra efficiency of the double worm-gear, the maximum torque of 175 ft. tons is obtained from a current of 270 amperes at 100 volts instead of 450 amperes as would be required with gearing of the ordinary type.

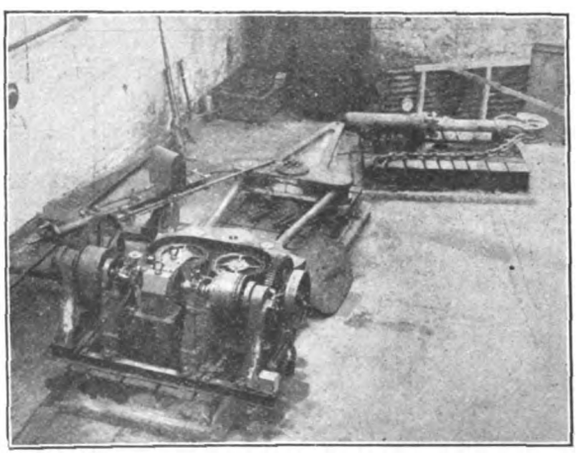

FIG. 3.—EXPERIMENTAL STEERING GEAR FOR 7 IN. RUDDER POST; WITH HYDRAULIC APPARATUS FOR TESTING.

These features are incorporated in the experimental steering gear shown along with testing apparatus in Figs. 3 and 4. The hydraulic cylinder for applying the artificial load is connected to the dummy tiller provided for test purposes by chain and is so lined off that the tiller leverage is the same when the rudder is hard-over at 35 deg. as when in the midships plane. It was found that the currents required to produce a pressure of 980 lb. per sq. inch on the 5 in. ram were 60 amperes when hard-over, and 90 amperes when amidships, corresponding to a change of leverage of 1·5 to 1. The time required to cross from hard-over to hard-over was 23 seconds when moving against the above load for 35 deg. out of the total of 70 deg., the voltage of supply being 90 volts. At this load, which corresponds to a torque of 20·4 ft.-tons in the rudder post, the overall efficiency is 48 per cent., indicating an efficiency of over 60 per cent. in the gear alone without hydraulic cylinder or motor. Under normal conditions the slip of the clutches when engaging was found to be small, estimated by means of a contact maker at between 1 and 2 revolutions, and up to the present, after a considerable period of testing in the works, no wear has had to be taken up on the fibre blocks. When the motor is loaded up to 150 amperes, corresponding to a torque of 50 ft.-tons, the clutches slip, and this current is not exceeded, even when the tiller is butted against a solid obstacle or when the chain is drawn taut from no load to full load.

The arrangements for controlling the clutches, also seen in Fig. 3, consist of one of Brown's improved hydraulic telemotors with a cut-off attachment coupled to the tiller crosshead. The switchgear, which is operated by mechanism equivalent to cam-gear, is enclosed in the small case (14 in. by 12 in. by 4 in.) mounted above the telemotor. In many vessels the telemotors are now attached to the deck beams overhead and this arrangement is very suitable for electrical steering as it keeps the switchgear free from water. Being fitted with carbon contacts, and dealing with such small currents, the switches should require but little attention. The cams require to be carefully arranged and free from backlash, to gain sensitive steering; and to stop the gear promptly a quick-acting brake, not necessarily very powerful, is used. The amount of stored energy is minimised by using light steel clutch discs and a motor with shunt regulation, running at its lowest speed when engaging and disengaging.

In installing electrical steering gear it is preferable to avoid the use of fuses or circuit breakers in the supply mains as these are liable to operate just when the use of the helm is most urgently required, and any possible damage to the electrical plant is greatly outweighed by risk in navigation. When a gear with friction clutches is used, a circuit breaker, adjusted for something over the limiting current of the clutches, may be fitted in the engine-room along with an auxiliary motor starter, so that the gear may be immediately restarted without leaving the main switchboard.

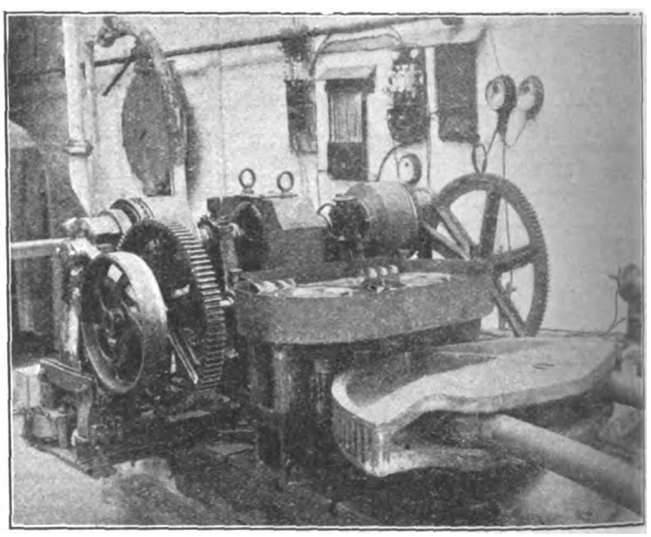

FIG. 4.—ELECTRICAL STEERING GEAR, SHOWING DOUBLE-WORM GEAR AND CROSSHEAD SECTOR.

In the foregoing notes it may be thought that the advantages of high efficiency are over-rated, but economy is not only valuable in itself and in the reduction in weight which it allows, but also on account of the increased reliability due to reduced wear and tear in the control gear and generating plant.

THE MANUFACTURE OF NITROGEN COMPOUNDS BY ELECTRIC POWER.*

BY E. KILBURN SCOTT.

Summary.—The author describes the electrical processes for the fixation of atmospheric nitrogen and urges the importance of establishing a factory in this country for the manufacture of nitric acid from the nitrogen of the air. Such works would render the country in time of war independent of overseas supplies for the manufacture of explosives. The author also considers the question of cost of electric power and thinks that the cost with a waste heat station might compare favourably with a supply from large hydro-electric stations.

The author here draws attention to several methods of fixing the nitrogen of the air with the help of cheap electric power, and he gives particulars of some of the products. The processes were started on a commercial scale in Norway and Italy about six years ago and they are now well established, the principal products being the artificial manures:—(*a*) Nitrate of lime, containing 12¾ per cent. nitrogen; (*b*) Calcium cyanamide or nitrolim, with 18 per cent. nitrogen. These manures are now being made at prices which compare favourably with the older artificial manures, such as nitrate of

* Abstract of a Paper read before Section G of the British Association at Portsmouth.

Digitized by Google

soda and sulphate of ammonia, when calculated on the nitrogen contents. For actual delivery to farmers, prices are perhaps not so favourable, because the quantities handled are small and the selling organisation is not so complete. The prejudices of the farmers have also to be overcome, and much propaganda expense is therefore necessary.

In the nitrate of lime process, as introduced by Birkeland and Eyde, the nitrogen is fixed *directly* from the air in the electric furnace, and nitric acid made from this fixed gas then acts on carbonate of lime. In the calcium cyanamide process, which was introduced by Frank and Caro, the nitrogen is first isolated from the air and then absorbed by carbide of calcium, itself an electric furnace product. It will thus be seen that a principal difference between the two processes is that the cost of raw materials for nitrate of lime is low, whereas in the case of calcium cyanamide the nitrogen has to be specially prepared by the Linde process, and the carbide of calcium by which it is absorbed (made from lime and coke or anthracite) costs about £6 a ton. The nitrate of lime process is certainly unique amongst industrial processes in using a raw material—nitrogen—that costs nothing; but, on the other hand, more electric energy is required for a given amount of nitrogen fixed. The prices of the resulting products are therefore very similar.

Many agricultural experts have tested these manures, and conclusively proved that when properly applied they are very valuable for increasing plant growth, also that they are especially useful for cereals—wheat, oats, &c., that require large quantities of nitrogen. As the Chilian deposits of nitrate of soda and the virgin soils of the world are rapidly becoming exhausted, and, at the same time, there is a steady increase in the number of wheat-eating people, it is fortunate that new sources of nitrogen manures have been developed. The output is small at present, but it promises to be the greatest development of electrical engineering science of the near future.

Nitrate of lime is usually added to the soil as a top dressing after the seed is in, whereas calcium cyanamide is dug into the soil about 10 days before planting. It is an interesting fact, however, that the best results are obtained by mixing the two manures together.

Besides manures, many other materials are made by these processes, and the writer specially draws attention to the manufacture of nitrogenous products for explosives. The nitric acid made by the nitrate of lime process can be concentrated to any value, and sold for manufacture of explosives, such as gun-cotton, dynamite, smokeless powder, &c.

Ammonium nitrate, which is the main constituent for the manufacture of safety explosives and laughing gas, is made by the very simple process of mixing the weak nitric acid that comes from the absorption towers of the Birkeland-Eyde process, with ammonia liquor obtained from English gasworks. The solution is crystallised and dried, and the resultant, containing 35 per cent. of nitrogen, is sold freely in England at £27 a ton. This material is also made from calcium cyanamide, and the Loteringen Works at Gerthe, near Bochum, produce about 2,000 tons per annum. As this does not come on the market, it is presumably all taken by the German Government as a substitute for nitro-glycerine.

At the present time this country is largely dependent on overseas supplies for the manufacture of explosives, and we should be in an extremely serious position in case of war. There is no reason whatever why a factory should not straightway be established in this country for the manufacture of nitric acid from the nitrogen of the air. Even if the product could not at first *compete* in price with existing supplies, the fact that it was a necessary addition to our national insurance against war would justify its establishment. Again, what is true of this country regarding the manufacture of explosives is applicable to other parts of the Empire, as, for example, Australia, New Zealand and South Africa.

In this connection, it is well to remember that various Government factories for the supply for the munitions of war, &c., do not pay from a competitive industrial point of view; yet everyone recognises that such factories must be kept going. In just the same way a factory for making nitrogenous products from the air by electric power should be started and kept going whether it pays its way or not. As a matter of fact, there is every reason for supposing that it would pay its way, and one of the objects of this Paper is to bring out that fact.

The author next proceeds to describe the processes for manufacturing nitrate of lime, as carried out at Notodden, and for calcium cyanamide, as carried out at Odda, in Norway.

It may be mentioned that calcium cyanamide is made in the following countries: Italy, France, Switzerland, Dalmatia, United States, Canada, Mexico and Japan, whilst in Germany alone there are about half a dozen factories.

Cost of Power.—As to whether it is possible to manufacture these nitrogen products in Great Britain, from a strictly commercial point of view depends on whether power can be obtained cheaply enough. In such countries as Norway and Switzerland, where there is plenty of water power, and no coal, there are several water-power plants which, having inexpensive hydraulic works, are said to produce power at £2 per kilowatt-year. For the total number of hours in a year £2 is equal to 0·055d., or $\frac{1}{18}$ of a penny per kilowatt-hour. At Notodden the power is said to cost 33s. per kilowatt-year, or 0·045d. per kilowatt-hour, and at Odda 30s. per electrical horse-power-year is paid for power.

It is interesting to compare these figures with the well authenticated statistics of the largest hydro-electro plant in the world, namely Niagara. For 1909, 362 million kilowatt-hours were sold for £210,000; of which 322 million units went to 33 electrochemical and metallurgical consumers at 0·133d. per kilowatt-hour. The remaining 40 million units were sold to electric light and traction consumers at an average price of 0·19d. per kilowatt-hour.

Now, electro-metallurgical works have usually a 100 per cent. load factor, and unfortunately there are very few such works in this country. There is, however, good reason to suppose that waste heat power stations in Great Britain could produce as cheaply as Niagara for such a load factor. Even to-day, electric energy is sold in Yorkshire and Durham at extremely low rates to collieries and ironworks, &c., where the load factor is nearer 33 per cent. than 100 per cent. The actual prices charged do not transpire publicly, but 0·25d. per kilowatt-hour has been mentioned.

Suppose an electric power plant of 10,000 kw. is erected at a cost of £10 a kilowatt, and that on a 33 per cent. load factor, the energy is sold for 0·25d. per kilowatt-hour. Now, let us see what would be a fair charge on a 100 per cent. load factor:—

The annual fixed charge for interest, depreciation, &c., may fairly be taken at 15 per cent., which gives £15,000. At a 33 per cent. load factor, this has to be spread over—33 per cent. of $(10{,}000 \times 8{,}760) = 29{,}200{,}000$ kw. hours, and therefore = 0·123d. per kilowatt-hour.

Deducting 0·123d. from 0·25d., which is the charge per kilowatt-hour, we get 0·127d. to cover the variable expenses.

Dividing the annual fixed charges by the total number of kilowatt-hours in a year namely, 87,600,000, we get 0·041d. Therefore, on a 100 per cent. load factor, the energy could be sold at 0·127d. + 0·041d. = 0·168d. per kilowatt-hour.

It may be suggested that nothing has been allowed for spare plant, but, as a matter of fact, £10 per kilowatt of plant installed is too high for a waste heat station. We are so accustomed to the absurdly large amounts that have been laid out on municipal electric light stations, &c., that the actual figure for which modern electric power plant can be installed comes as a surprise.

Even so long ago as 1906, the Manchester Corporation extension station cost only £12 per kilowatt of plant to instal, as shown by Mr. Pearce's figures:—

Generating machinery, turbine, condenser, alternator, &c.	£3·75
Boilers, economisers, superheaters, steam pipes, coal and ash conveyors, foundations, &c.	2·25
Switchgear for generators and feeders	0·55
Elaborate buildings with accessories	5·05
	£12·05

Prices of electrical machinery have come down very much since then, and there has also been a decline in the prices of mechanical parts of the plant, such as boilers, turbines and steam accessories. The figure of £5 per kilowatt for land and buildings and accessories is also high, because municipalities usually erect buildings that are much too elaborate. If fresh tenders for the Manchester plant were obtained to-day, the total would probably not exceed £10 per kilowatt installed.

Waste Heat Station.—The above is for a complete steam plant, and with the same data it is interesting to see how much a waste heat station using waste steam from, say, rolling mills as at Sir Bernard Samuelson's works would cost.

Generating machinery, turbine, condenser, alternator, &c.	£3·75
Steam reservoir and a small amount of piping, no boilers	0·20
Switchgear for generators, feeders	0·55
Plain shell building, no chimney	2·00
	£6·50

The figures for a waste heat station using gas from blast furnaces or coke ovens, would probably cost about the same, for although the gas engine and alternator might cost a little more, there is no condenser. There would, of course, be gas-cleaning apparatus, provision for cooling water, and a small amount of piping, but these are small items. The switchgear and buildings should be about the same as for the waste steam station.

Analyses of electrical accounts of the majority of existing power plants show that the interest and depreciation with sinking fund in the case of municipal plants form the largest items in cost per unit

Digitized by Google

generated. If, therefore, the initial cost of the plant can be brought down from, say, £50 a kilowatt, which is a fair average of existing plants, to, say £6 a kilowatt, which seems feasible, then the cost of electric power should fall to a figure that is comparable with the most favoured hydro-electric plants.

One reason for the low prices for electric energy in Norway is because the harnessing of the power can be done so easily; but as a matter of fact, very few hydro-electric plants are built for as low as £10 per kilowatt installed. Even in the United States, where there is much water power and the harnessing of it has reached a very high pitch, most of the large power houses in that country depend on steam.

As water power becomes more developed, the tendency will be for the cost of power generated in that way to increase. One reason is that the owners of water powers will want more for their rights, and another is that, as industries are attracted to the centres where the water power is available, there will be greater competition for the power. At present they are mostly situated in inconvenient places. Steam and gas plants, on the other hand, can always be installed close to the market for power and where freights for raw materials and finished products are low. Therefore, as the generating units become larger and power becomes centralised in larger stations the cost per kilowatt-hour generated should steadily decrease.

The writer considers that the time is ripe for the establishment of many electrochemical and electro-metallurgical processes, which at present are only carried on abroad. Amongst these the manufacture of nitrate manures, and especially nitrogen compounds for explosives are very important, especially the explosives, for reasons put forward in this Paper.

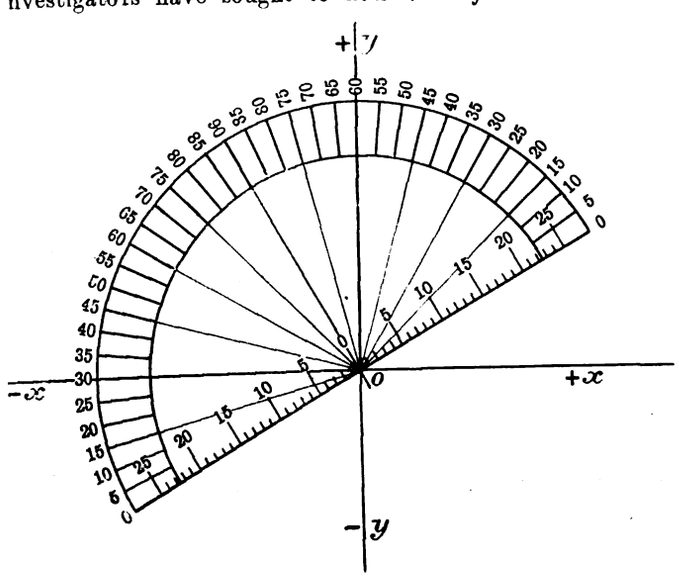
A SIMPLE GRAPHICAL METHOD FOR THE HARMONIC ANALYSIS OF A CYCLIC FUNCTION.

BY J. R. ASHWORTH, D.SC.

In the harmonic analysis of a curve the determination of the constants in the expression—

$$A_0+A_1\sin(\theta+\phi_1)+A_2\sin(2\theta+\phi_2)+\ldots\ldots$$

presents some tedious arithmetical work which numerous nvestigators have sought to minimise by various devices.



Of the graphical methods which have been suggested a good example is given by J. Harrison (" Engineering," Vol. LXXXI., 1906, p. 201), in which the ordinates of the curve are drawn as vectors at equal angles from a given point and from their components, obtained by graphical projection on two rectangular axes, the values of A and ϕ are calculated.

This method may be still further simplified and nearly all arithmetical work eliminated by the following procedure. Let the period of the given curve be divided into n equal elements, and let y_1, y_2, $\ldots\ldots y_n$ be the ordinates of this curve. They may be measured advantageously as the excess over the least, so that all quantities are positive, one of course being zero. These ordinates are then to be treated as co-planar forces radiating from a common centre at angles θ, 2θ, 3θ, &c., measured from a horizontal axis in the counter-clockwise direction, and then *by the polygon of forces* their resultant is to be found by drawing the line which closes the polygon. This resultant in magnitude will be $n/2$ times the amplitude A, of the first term of the analysis, and the angle ϕ_1 is determined by the relation $\tan\phi_1 = \cot\alpha$, where α is the angle which the resultant makes with the positive part of the horizontal axis.

The constants of the second term are to be found in the same way, the vectors now being placed at angles 2θ, 4θ, $\ldots 2n\theta$. The third and higher terms are treated similarly.

The practice of the method is facilitated by using a transparent protractor like the one figured in the text. Suppose, for example, that the period of the given curve is divided into 12 equal parts and that the ordinates are 9·8, 6·5, 4·3, &c., then. θ being equal to 360/12 or 30 deg., the line on the protractor marking 30 deg. is put along the horizontal axis, the centre of the scale being at the origin, and the length 9·8 is marked with a needle on the straight edge. The zero of the protractor is then pushed up to this needle, the protractor turned so that the line 30 deg. passes through the origin, and the length 6·5 is marked with a second needle. The first needle being removed, the zero of the scale is pushed up to the second one, the line 30 deg. is made to pass through the first prick and the third length marked off. The proper placing of the zero is very quickly performed by having a projecting lip on the straight edge of the protractor at the zero of the scale (which must also be the centre of the angular graduations). Proceeding step by step in this way the polygon is smoothly and rapidly constructed and the resultant easily found.

The accuracy of the final result depends in part on the skill of the operator, but if the angle θ is not very small, and if the values y_1, y_2, $\ldots y_n$, are read off on an enlarged scale no serious errors will be made.

The number of operations can be reduced to one-half, or even less for the higher terms, by a preliminary grouping of the vectors y_1, y_2, &c., those in the same line being added algebraically, but as this may introduce negative quantities, some care has to be exercised to avoid mistakes in carrying out the graphical work.

In engineering practice, where the higher harmonics are often unimportant and not required, this graphical process of harmonic analysis will be found useful, and it is exceedingly rapid and easy to carry out.

SOME PRELIMINARY NOTES ON A STUDY AS TO HUMAN SUSCEPTIBILITY TO VIBRATION.*

BY W. POLLARD DIGBY AND CAPTAIN H. RIALL SANKEY.

Summary.—A few notes are given on the results of some preliminary work made on the susceptibility of human beings to vibration. Certain distinctive general tendencies seem to be clearly indicated and are enunciated. The work is being continued.

In regard to all the senses of taste, sight, sound or smell, the range of the individual sensitiveness of human beings is recognised as a matter of considerable variation. Even those with no pretence to scientific training class their fellows as short or long sighted. In regard to sound, the degree of discrimination of different people, both at any one age or at different ages, is a matter of much anthropometric interest. The physiological effects of mechanical vibration are probably worthy of investigation, but before the medical aspects can be discussed, fairly exhaustive preliminary investigations are necessary. It has long been known that different persons are affected in different manners by the same conditions of vibration. So far as the authors are aware this subject has not yet been the subject of any very definite study and investigation.

In the course of his professional work, one of the authors had occasion to design a portable instrument for taking permanent records of the amplitudes of vibration of steam turbines and reciprocating engines, and of measuring the effect of such vibrations on neighbouring buildings. On showing this to his co-author the latter referred to a statement by Admiral Melville that the effect of vibration depends upon the frequency and on the actual amount

* Paper read before Section G (Engineering) of the British Association at Portsmouth.

Digitized by Google

of linear motion, and that the frequency multiplied by the amount of motion was a constant.*

Further, in the same Paper, which deals with steamship vibrations, Admiral Melville quotes Mallock's statement in regard to the Central London Railway cases, that vibrations rarely exceeding a thousandth of an inch, when the frequency is over 10 per second, are a genuine source of annoyance.

After discussing Admiral Melville's dictum (which one presumes applies to normal persons) the authors decided to pursue the present study. The phrase "human susceptibility to vibration" was coined to cover the range of sensitiveness of various people to vibrations of short duration of different amplitude and frequency, together with their opinions as to when those vibrations approached or exceeded the point of being a nuisance.

At the time of writing this Paper only a certain number of cases have been studied. The information collected is not yet sufficient for the enunciation of a comprehensive law, but it does suffice for the propounding of certain general statements.

At the outset the authors found it necessary to adopt both verbal standards of degree of vibration and precise units of measurements in order that the comparative value of the conceptions of the verbal standards by different persons might receive some co-ordination.

The verbal standards of degree of vibration selected were as follows:—(1) Imperceptible, (2) Very faintly perceptible, (3) Faintly perceptible, (4) Perceptible—not a nuisance, (5) Perceptible—just a nuisance, (6) Perceptible—distinct nuisance, (7) Perceptible—serious nuisance, (8) Perceptible—excessive nuisance.

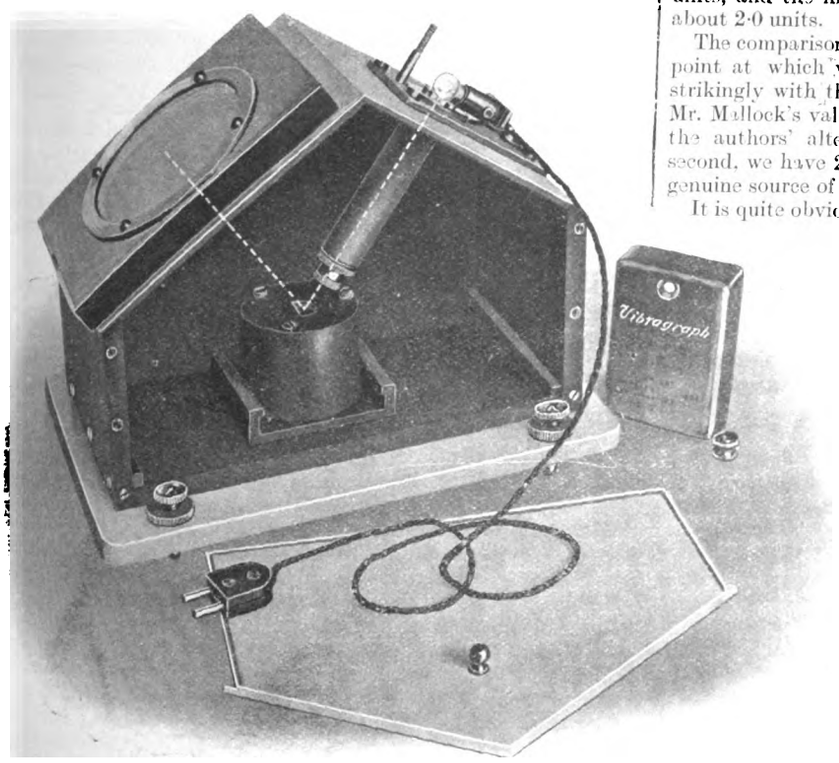


FIG. 1.—VIBRAGRAPH OF MESSRS. SIEMENS BROTHERS & CO.

The precise unit of measurement adopted by the authors as a mechanical unit of intensity of vibration is a vibration having a maximum linear amplitude of one-tenth of a millimetre at a frequency of 10 cycles per second. (Alternatively, and of course identical in value, would be the definition of one millimetre at 1 cycle per second).

Referring to the verbal standards of degree of vibration, it should perhaps be explained that the series starts at unity and not at zero, because the apparatus used in these measurements indicates vibration not felt by any persons resting the palm of the hand on a table vibrating under the effect of a variable speed electric motor placed on it.

As the writers have stated, only a certain number of individuals have so far been investigated. While this number does not permit the enunciation of definite laws, certain distinctive general tendencies seem to be clearly indicated. Among these may be noted the following:—

1. That for various individuals the range of vibration rated as degree 1 (*i.e.*, as imperceptible) is a wide one. Thus upwards of 21 cases are recorded in which a vibration of from 0·10 to 0·20 units is classed as imperceptible, while six cases classify vibrations in this range as degree 2, and five cases as degree 3.

2. That there is also wide variation in regard to vibration rated as degree 2 (*i.e.*, as very faintly perceptible). Three cases class this as under 0·10 units, six as between 0·10 and 0·20, six as between 0·40 and 0·50, while seven cases could only distinguish vibrations in excess of 0·50 units.

3. That each individual shows a "fatigue" effect, and gives expressions of opinion as to the degree of vibration after 30 or 40 minutes of observation which are not consistent with his previous expressions of opinion. In general these point to a diminished sensitiveness.

4. That individuals can be classed into the broad classes of (*a*) delicate and (*b*) coarse perceptiveness. The former class, although capable of discrimination in regard to vibrations of small intensity, give uncertain and contradictory readings when the vibrations exceed a certain amplitude. The latter class, while distinguishing clearly between vibrations of differing large intensities, cannot feel vibrations of small intensity, and are not always consistent in their classification of vibrations of medium intensity.

5. That so far the general consensus of opinion points to the degree of vibrations classed as 5 (perceptible—just a nuisance) being reached for a mean intensity of 1·0 units. The lower range for persons of delicate perceptiveness is in the neighbourhood of 0·70 units, and the higher range for persons of coarse perceptiveness is about 2·0 units.

The comparison of the mean value of an intensity of 1·0 unit as the point at which vibration just becomes a nuisance compares very strikingly with the value quoted by Admiral Melville. Converting Mr. Mallock's value of one mil multiplied by cycles per second into the authors' alternative of millimetres multiplied by cycles per second, we have 2·54 units of intensity of mechanical vibration as a genuine source of annoyance.

It is quite obvious that the present study is purely of a preliminary nature. For the purposes of this research, perceptiveness to vibration has been estimated by the sense of touch of a person's hand resting on a table, the table being disturbed by a variable speed electric motor. Flywheels attached to each end of the motor shaft have concentric rings of holes drilled and tapped in them so that the amount of the unbalanced force can be varied at will. In one or two cases observations have been made of the opinion expressed when the elbows of the subject rested on the table, the palm of the hand supporting the face. Another interesting alternative (and there are many such) would be for the subject to sit on the table.

In the further pursuit of this investigation it will probably be of interest to ascertain:—

1. To what extent the susceptibility of any single individual is influenced by conditions of physical health, the effect of over-work or railway travelling.

2. To what extent age and sex are modifying factors.

3. Whether occupation has any broad general effect, *i.e.*, whether say surgeons, barristers or engineers (regarded as classes) differ to any marked degree from the mean value obtained.

All the present vibrations have been due to practically pure sine waves at a stated frequency, which latter was kept of constant value at the time of observation. Nothing has yet been done to simulate in the laboratory the super-imposition of waves giving a third or fourth harmonic. Neither has anything yet been done to simulate in the laboratory a recurring intermittent vibration such as that produced when propellers or the exhausts from non-condensing engines approach, reach and get out of synchronism with one another.

The authors hope to pursue this research along the lines indicated. They will be glad if members of this Association and their friends care to visit Mr. Digby's laboratory on either Monday or Thursday afternoons after October 1st, and form the subjects of experiment. It is desirable from many points of view, and not least the legal one, that there should be some definition of what exact intensity constitutes a nuisance. It is not possible to deal with more than, say, three cases in any afternoon, and to prevent waste of time the authors would therefore be glad of notice of intending calls. For the enunciation of a general law they would like to deal with a

*"Engineering," Vol. LXXV., 1903, p. 33.

Digitized by Google

total of 100 to 150 cases. The nature of the experiments will be demonstrated in an adjoining room.

Attention may be drawn in connection with the above Paper to the "Vibragraph" of Messrs. Siemens Brothers & Co. This is claimed to be the first practical instrument for measuring and recording vibration in definite units.

Fig. 1 herewith illustrates the complete instrument. A mercury cup is provided with a floating mirror, pivoted so as to avoid lateral movement and the mercury ripples caused by vibration result in an angular movement of the mirror. The beam of light emanating from the small glow-lamp, and reflected by the mirror, will therefore record on photographic paper a straight line if the vibration is in one plane only, or a complex figure if the vibration be in planes at different

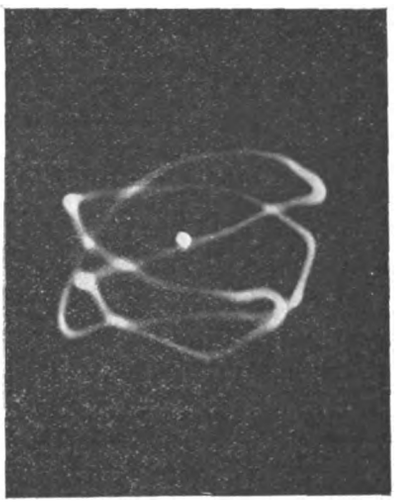

FIG. 2.—VIBRAGRAM FROM CRANK CASING OF ENGINE DRIVING ALTERNATOR.

angles, as will usually be the case in practice. In this connection Fig. 2 is interesting as showing a vibragram from the crank casing of an engine driving a 1,250 k.v.a. alternator at 188 revs. per min. [The scale is 1 in.=77mils. (1·96 mm.) actual vibration.] When records are not required a screen permits of direct visual observations.

We understand that the apparatus has proved very satisfactory in practical tests extending over 18 months; among others, for two large municipal electric supply undertakings in connection with litigation in respect of alleged nuisance through transmitted vibration of the central station.

STROBOSCOPIC METHODS OF MEASURING THE SLIP IN INDUCTION MOTORS.*

BY A. BRUCKMANN.

Many methods have been described for measuring slip, but none are altogether satisfactory. One of the most interesting is the stroboscopic method. A black disc is mounted directly on the spindle of the rotor, and on this disc there is a white line, drawn either along a diameter or along a radius, the whole being illuminated by an arc lamp which is fed with alternating current of the same frequency as that supplied to the stator. The brightness of the illumination given by the lamp varies between a maximum and a minimum, the frequency of the variation being twice that of the source of supply of alternate current, seeing that the negative impulses also contribute maximum effects. The white diameter or radius, as the case may be, appears brightly illuminated every time that the arc lamp gives out its maximum light, and the observer therefore notices on the disc as many images of the radius as correspond to the number of variations in the light over one revolution. At synchronism the effect produced is that of a stationary star, or wheel, the number of the spokes being equal to the number of pairs of poles on the stator. If the motor is then loaded the wheel begins to turn at a rate which depends on the amount of slip. By noting the rate at which the wheel is seen to revolve, the slip can be calculated from the following formula:—

$$s\% = \frac{n_s - n_r}{n_s} 100,$$

where n_s is the speed of the rotating field and n_r the rate of revolution of the rotor.

If the number of pairs of poles is small, the star or wheel rotates so fast that it is difficult to count the number of revolutions if the slip is considerable: on the other hand, if the number of poles is considerable, the wheel has so many spokes that again the work of counting is not very easy. For instance, suppose the slip to be 6 per cent. and the periodicity 50, the motor having only a single pair of poles, the revolutions appear to be at the rate of 360 a minute, seeing that the images appear twice at their maximum brightness for every complete cycle of the alternating current. Take, again, a motor with six poles, the other conditions being as before, the rate of revolution is now 60 per minute, but the wheel has six spokes, which makes the counting almost as difficult as before. There is also another point to be considered: at 50 cycles the sluggishness due to the heat-conductivity of the carbons is considerable, and produces a sort of equalising effect, so that the separate images are not as distinct as they might be.

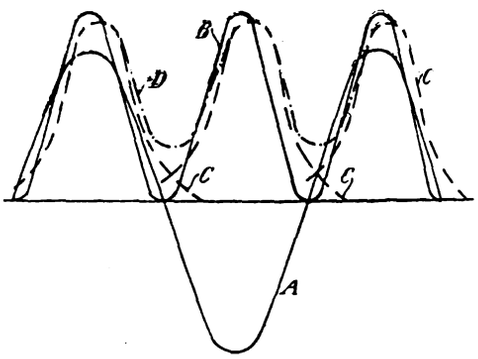

FIG. 1.—SHOWING CURVES OF ILLUMINATION FROM AN ALTERNATE CURRENT ARC.

There is, however, a simple method by which the number of spokes in the wheel may be halved, and this method indirectly has another advantage, as will be explained. According to this proposal, with a six-pole motor the wheel would have only three spokes, and with a considerable slip it is possible to count the revolutions quite easily, and, moreover, the images stand out very distinctly on the disc. As has been stated above, the negative currents give also a maximum illumination of the disc in exactly the same way as the positive maximum impulses. Now if the negative currents can be suppressed the images which correspond to the negative maxima will be equally suppressed, and the images corresponding to the positive maxima will be all the more clearly defined. Figs. 1 and 2 explain this.

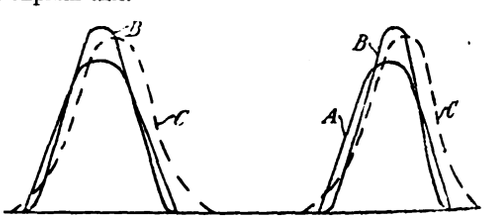

FIG. 2.—SHOWING CURVES OF ILLUMINATION FROM AN ALTERNATE CURRENT ARC WITH THE NEGATIVE CURRENT SUPPRESSED.

Let A represent the wave of alternate current, while B represents the square of the alternate current, which corresponds to the brightness of the illumination. In Fig. 1 the curve C shows the illumination to a first approximation, but owing to the sluggishness of the heat-conductivity of the carbons, the true curve of illumination is given by D, which never falls as low as the datum line. If, however, suitable means are employed for suppressing the negative impulses things are very different, as shown in Fig. 2, where the positive impulses alone are shown. The arc now receives no current during every alternate half-period, during which time the carbons have time to cool and no image of the revolving radius exists, the corresponding spoke of the wheel being therefore suppressed. The curve showing the illumination is correspondingly modified, as shown in Fig. 2.

It remains to describe the means by which this virtual suppression of the negative impulses can be produced. Something can be done

* Abstract of an article in the "Elektrotechnische Zeitschrift." We would refer our readers to an article on this subject by Dr. C. V. Drysdale, which appeared in THE ELECTRICIAN, Vol. LV., p. 734, 1905. —ED. *E.*

Digitized by Google

by inclining the carbons at suitable angles, so that, whereas the light from the one is reflected on the disc, the light from the other is thrown in another direction, where it largely escapes the disc. In this way a wheel is produced the spokes of which have alternately a varying degree of brightness. But a far better method consists in the use of the aluminium cell. Let us suppose such a cell to be inserted in the circuit, as shown in Fig. 3. As is well known, current now passes only in the one direction, and the number of the spokes in the wheel is at once halved. A further advantage of this method lies in the fact that the lamp now works more or less as a direct-current lamp, and if the carbon which is connected to the aluminium cell is placed uppermost the effect is intensified, owing to the fact that the convection currents in the surrounding air tend to heat the upper carbon and cool the lower one. The tips of the carbons approach somewhat to the characteristic shapes associated with direct current, and the maximum illumination is always thrown in

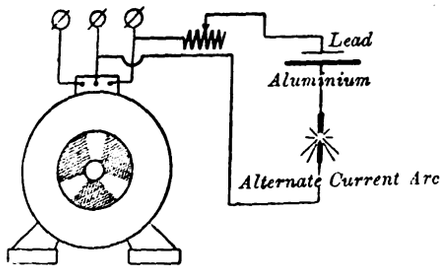

FIG. 3.—SHOWING THE REVOLVING "WHEEL" OR "STAR," TOGETHER WITH THE LEAD-ALUMINIUM CELL.

one direction. The electrolytic cell is easily prepared from ordinary aluminium and lead plates, and a saturated solution of bicarbonate of soda may be used as the electrolyte with a current-density of 0·05 ampere per square centimetre. The volume of the electrolyte should not be too small in order to keep it reasonably cool.

MULTIPLEX TELEPHONY AND TELEGRAPHY BY MEANS OF ELECTRIC WAVES GUIDED BY WIRES.*

BY GEORGE O. SQUIER.

Summary.—The author describes a series of experiments on the effect of superimposing upon ordinary telephone circuits electric waves of ultra-sound frequencies.

The limits of audibility, being physiological functions, are well known to vary considerably, but they may be taken to be in the neighbourhood of 16 complete cycles per second as the lower limit and 15,000 to 20,000 cycles per second as the upper limit. If, therefore, there are impressed upon a wire circuit for transmitting intelligence harmonic E.M.F.s of frequencies between 0 and 16 cycles per second, or, again, above 15,000 to 20,000 cycles per second, it would seem certain that whatever effects such electric wave frequencies produced upon metallic lines, the present apparatus employed in operating them could not translate these effects into audible signals.

There are, therefore, two possible solutions of the problem of multiplex telephony and telegraphy upon this principle by electric waves—viz., by employing (1) electric waves of infra-sound frequencies, and (2) those of ultra-sound frequencies. One great difficulty in designing generators of infra-sound frequencies is in securing a pure sine wave, as otherwise any harmonic of the fundamental would appear within the range of audition. Furthermore, the range of frequencies is restricted, and the physical dimensions of the tuning elements for such low frequencies would have a tendency to become unwieldy.

The electromagnetic spectrum at present extends from about four to eight periods per second, such as are employed upon ocean cables, to the shortest waves of ultra-violet light. In this whole range of frequencies there are two distinct intervals which have not as yet been used—viz., frequencies from about 3×10^{12} of the extreme infra-red to 5×10^{10}, which is the frequency of the shortest electric waves yet produced by electrical apparatus, and from about 80,000 to 100,000 cycles per second to about 15,000 to 20,000 cycles per second. The upper limit of this latter interval represents about the lowest frequencies yet employed for long-distance wireless telegraphy.

Within the past few years generators have been developed in the United States giving an output of 2 kw. and above at a frequency of 100,000 cycles per second, and also capable of being operated satisfactorily at as low a frequency as 20,000 cycles per second. Furthermore, these machines give a practically pure sine wave.

The necessary conditions for telephony by electric waves guided by wires are an uninterrupted source of sustained oscillations, and some form of receiving device which is quantitative in its action. In the experiments described in multiplex telephony and telegraphy it has been necessary and sufficient to combine the present engineering practice of wire telephony and telegraphy with the engineering practice of wireless telephony and telegraphy.

The frequencies involved in telephony over wires do not exceed 1,800 to 2,000, and for such frequencies the telephonic currents are fairly well distributed throughout the cross-section of the conductor. As the frequency is increased the so-called "skin effect" becomes noticeable, and the energy is more and more transmitted in the ether surrounding the conductor. It has been found impossible to superimpose upon the ordinary telephonic wire circuits now commercially used electric waves of ultra-sound frequencies without producing any harmful effects upon the operation of the existing telephonic service. Fortunately, therefore, the experiments described below are constructive and additive, rather than destructive and supplantive.

Apparatus.—Under a special appropriation granted to the Signal Corps by Congress in the Army Appropriation Act of 1909, a small research laboratory has been established at the Bureau of Standards, in the suburbs of the city of Washington. This laboratory is equipped with the latest forms of apparatus now employed in the wireless telephone and telegraph art, and also with the standard types of telephone and telegraph apparatus now used upon wire circuits. The small construction laboratory of the U.S. Signal Corps is located at 1710 Pennsylvania-avenue, and is also equipped with the usual type and forms of apparatus used in transmitting intelligence by electrical means. Each of these laboratories is supplied with a wireless telephone and telegraph installation with suitable antennæ. In addition, these two laboratories are connected by a standard telephone cable line about 7 miles in length, which was employed in the experiments described below.

The high-frequency alternator used is a special form of the inductor type designed for a frequency of 100,000 cycles with an output of 2 kw., making it adapted for use in wireless telephony or telegraphy.*

The telephone line used is made up of the regular standard commercial equipment, and consists of paper-insulated twisted pairs in lead-covered cable, placed in conduit in the usual manner employed for city installation. The air-line distance between the two laboratories is a little over 3 miles (4·8 km.), but the telephone line, by passing through three exchanges, covers about 7 miles (11·27 km.).

DUPLEX-DIPLEX TELEPHONY OVER WIRE CIRCUITS.

Any plan which permits the present telephone system to remain intact and superimposes thereon additional telephone circuits would possess cardinal advantages. Accordingly, the first experiments were directed to as whether or not it is possible to superimpose upon the minute telephonic currents now employed in telephony over wires, electric waves of ultra-sound frequencies without causing prohibitive interference with the battery telephone currents.

With a collection of telephone receivers ranging from about 50 to over 8,000 ohms and of a variety of designs a series of tests was made. It was found, in general, that alternating currents of frequencies ranging from 30,000 to 100,000 cycles per second, when coupled conductively, inductively or electrostatically to local circuits from the generator produced absolutely no perceptible physiological effects in the receivers, excepting only that at certain of the lower frequencies a distinct audible note could be faintly heard in one of the receivers of about 250 ohms resistance. This note was found to be due to a slight variation of the amplitude of the high-frequency current of the generator, and appeared to be caused by a very slight vibration of the rotor as a whole in the magnetic field of the generator. It was almost entirely removed by the simple device of opening out the stator, which increases the clearance and materially cuts down the flux of the machine. In practice it is a distinct advantage, however, to have a trace of this note still left on the high-frequency side of the circuit, otherwise there is no ready means of determining at the receiving end of the cable line whether or not the high-frequency current is present on the line.

The next step consisted in introducing various forms of detectors, such as are now used in wireless telegraphy, between the telephone receiver itself and the energising circuit. Since the frequencies here considered are entirely above audition, it was necessary, in order to produce a physiological effect, to introduce another element in this transformation—viz., some method of modifying the continuous train of sustained oscillations from the generator into groups or trains, the period of which falls within the limits of audition. Since it is well known that the human ear is most sensitive at a period of

* Abstract of a Paper presented at the Annual Convention of the American Institute of Electrical Engineers.

* *See* THE ELECTRICIAN, July 16, 1909, p. 541.

Digitized by Google

about 500 cycles per second, or 1,000 alternations, interrupters giving this frequency were employed.

Experiments were next made over local circuits at a range of frequencies from 20,000 to 100,000 per second, with the result that speech was transmitted very satisfactorily. Upon removing the detector from the above arrangement all perceptible effect in the telephone receiver ceased; in fact, no arrangement of connections of a telephone receiver to such a high-frequency circuit which did not include some form of detector was found to be operative for telephony unless certain low resistance telephones were used, in which case the speech was so much weaker as to be of an entirely different order of magnitude. The presence of a detector in this chain of operations is not absolutely necessary in the case of telegraphy, since, if the interrupter automatically produces a definite number of wave-trains per second, each train consisting of at least several complete oscillations, an effect may be produced upon a telephone receiver directly without a detector.

The test line was then taken and the machine was run at a frequency of 100,000 cycles per second, one wire of the telephone cable being connected to one terminal of the secondary of an air-core transformer, the other terminal being connected to earth. At the receiving end of the line this wire was connected direct to earth through a "perikon" crystal detector, and a high-resistance telephone receiver of about 8,000 ohms was shunted around the crystal. In this preliminary experiment no attempt was made at tuning, either at the transmitting end or at the receiving end of the line.

A loose coupling was employed between the two circuits at the transmitting end, and the line circuit adjusted by varying the coupling until the current in the line was 20 to 30 milliamperes. With this arrangement (1) telegraphic signals were sent and easily received, and (2) speech was transmitted and received successfully over this single wire with earth return. The actual ohmic resistance of the line apparently played an unimportant part for telegraphy at 100,000 cycles.

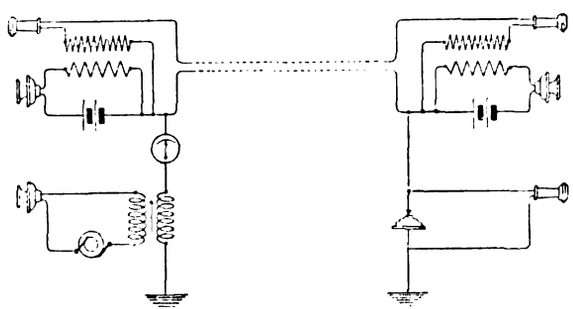

FIG 1.

Duplex Telephony, Using One Earthed Circuit.—To determine the fact that electric waves of ultra-sound frequency produce no perceptible effect when superimposed on the same circuit over which telephonic conversation is being transmitted, the next step was to use such a train of sustained oscillations as the vehicle for transmitting additional speech over the same circuit. For this purpose the twisted-pair telephone line was equipped with a complete standard local battery telephone set (Fig. 1). When the earth connections were introduced without tuning elements therein the metallic circuit experienced the usual disturbances found under city conditions, but it could be reduced to silence again by introducing in the earth connections the necessary tuning elements of magnitudes suited to wireless telegraphy.

Next, the twisted-pair telephone line was equipped with a complete standard local battery telephone set, as installed for commercial practice, with the exception that the local battery circuit of the transmitter telephone set was opened and a few turns of coarse wire inserted in series with the two dry cells which are normally used, as shown in Fig. 2. Inductively connected with this coil was the armature circuit of the generator. A hot wire milliammeter was placed in the line circuit to indicate the magnitude of the high-frequency current which was flowing on the line. With this arrangement tests were made to determine whether or not there were any effects upon the transmission of speech, due to superimposing high-frequency currents upon the battery telephone sets. With an operator at each end of the line, using the equipment in the regular commercial way, the direct-current voltage and the alternating-current voltage in series with it in the primary circuit of the transmitter were varied individually and relatively in a variety of ways, with the striking result that just at the point where the direct-current voltage was decreased, so that no sounds were received, the line became absolutely silent, although the alternating voltage in the circuit was at its largest value, or, again, speech would reappear at the receiving station at the moment when sufficient direct-current voltage was introduced to produce it, and the simultaneous presence of both the maximum direct voltage and maximum high-frequency voltage in a circuit produced exactly the same result as the maximum direct-current voltage did alone. When, however, the high-frequency current in the local circuit was forced to a point which caused "burning" in the transmitter itself, then, and then only, did the high-frequency current in any way interfere with the transmission.

By transferring this coil from the local circuit of the telephone set directly into the line itself, so that the high-frequency oscillations would be superimposed upon the line beyond the iron-cored induction coil of the telephone transmitter, it was not possible to detect the presence or absence of high-frequency currents.

As a test under severest conditions the effect was noted upon speech received at the same station at which the high-frequency current is being impressed, for here are the attenuated telephonic currents at the receiving end of the telephone line, on which is superimposed a high-frequency current of vastly greater magnitude at the same point. No effects of any kind could be detected under these conditions. From the above experiments it appears that in any attempt at multiplex telephony by means of electric waves of ultra-sound frequencies superimposed upon the minute telephonic currents employed in battery transmission there is nothing to fear from disturbances of such currents upon the operation of the ordinary battery equipment.

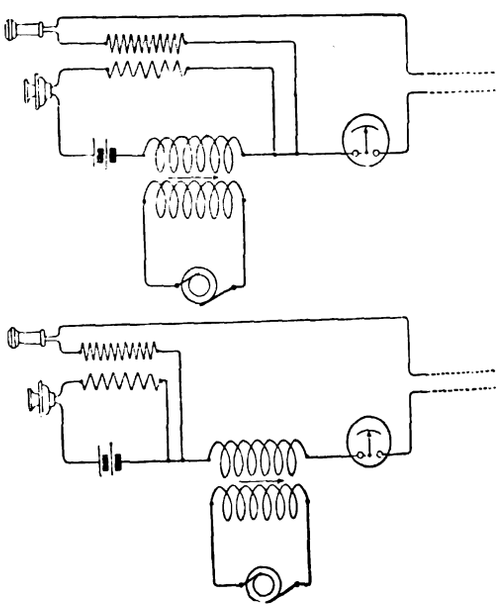

FIG. 2.

Silent Earth Circuits.—In providing tuning elements for earth connections there is at the same time afforded a certain means of eliminating any harmful disturbances from the earth, for the condensers employed for tuning to frequencies above audition possess an impedance to the frequencies involved in speech and also any disturbances from the earth, which effectively prevents the passage of any disturbance of audible frequency. These condensers offer a comparatively free passage to the electrical oscillations of the frequencies here being considered. When such earth connections are selectively tuned with the line to frequencies entirely above audition it is evident that no audible frequencies, either in the earth itself or from the line, can pass.

The point was now reached where the road was clear for duplex telephony, and for this purpose the apparatus and methods employed in wireless telephony were applied to one of the wires of the metallic circuit as though it were an antenna. The actual arrangement of this circuit is shown in Fig. 3, in which G is the source of sustained high-frequency oscillations, C′ is the tuning condenser of the oscillatory circuit, L′ is the tuning inductance of the oscillatory circuit, P is the primary of the oscillation transformer, A is the ammeter, M is the transmitter microphone, S is the secondary of the oscillation transformer in the line circuit, C is the tuning condenser in the line circuit, L is the tuning inductance in the line circuit, A′ is the ammeter in the line. At the receiving end of the line C_1 is the line tuning condenser, L_1 is the line tuning inductance, P_1 is the primary of the oscillation transformer, S_1 is the secondary of the oscillation transformer, L_1' is the tuning inductance in the oscillatory circuit, e_1' is the tuning condenser in the oscillatory circuit, between which and the telephone F′ the detector D is operatively connected; E is the earth connection.

Digitized by Google

The local battery telephone sets are connected across the two-line wires in the usual manner. In both sets 1 is the microphone transmitter, 2 is the local battery, 3 is the induction coil, 4 is the ringing system, including the bell and hand generator, 5 is the switch-hook, 6 is the telephone receiver.

It was found that cross-talk was heard in the detector circuit from the battery transmitter at the transmitting end when the detector circuit alone was connected directly to earth from the line without any tuning coil or condenser. If, however, the tuning condenser was inserted, this cross-talk entirely disappeared even though the tuning coil was not inserted. This is because the impedance of the small tuning condenser is large for telephonic frequencies, while the tuning coil impedance admits these telephonic frequencies. Both elements of tuning are required for selective absorption of energy, so that the high-frequency circuit is available as an additional telephonic circuit. With this arrangement talking in the transmitter of the high-frequency side of the system was heard only in the detector and there was no cross-talk from the ordinary local battery circuit. Similarly, there was no effect of the high-frequency transmission on

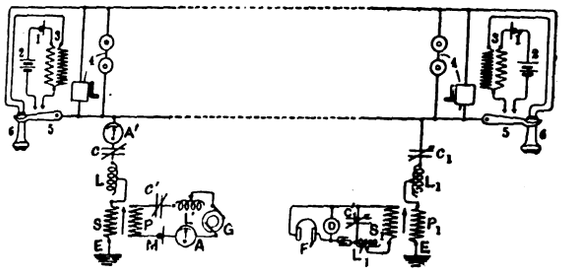

FIG. 3.

the local battery transmission, and the two telephonic messages were completely separated. Both circuits were entirely free from earth disturbances.

The volume of speech at the receiving end of the cable is greatly increased by the simple device of inserting the transmitter in the dynamo circuit and operating this circuit at or near resonance. In addition, the coupling at both transmitting and receiving stations should be so designed as to permit adjustment for optimum.

The frequency used in this experiment was about 100,000 cycles per second. The talk on the regular battery circuit was of the usual high standard both ways, so that the only reason at this point why complete duplex-diplex telephony was not obtained was the fact that there was no high-frequency dynamo available at the laboratory. There is, however, available at this laboratory one of the latest forms of the high-frequency arc, and accordingly this was arranged with suitable electromagnetic constants to give a period of about 71,000 cycles per second. This source of high-frequency E.M.F. was induced upon the high-frequency line wire in a similar

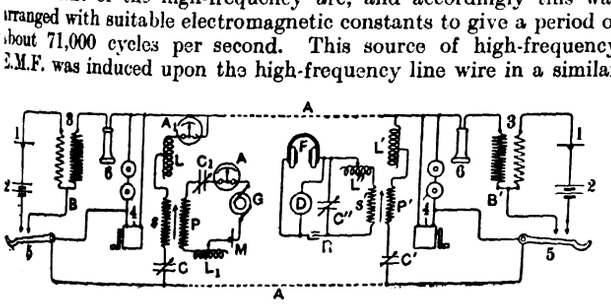

FIG. 4.

manner to that described in the station at the Bureau of Standards, with the result that one of the wires of the twisted-pair was made to carry simultaneously the battery telephonic currents from the two transmitters, the high-frequency oscillations of about 100,000 cycles per second, applied at the Bureau of Standards, and the high-frequency oscillations of about 71,000 cycles per second, applied at the laboratory. No influence from these conditions was perceptible upon the excellence of the battery transmission and reception of speech either way.

Duplex Telephony, Using Metallic Circuit.—The next step was to remove entirely the earth connections from the metallic circuit and superimpose both telephonic circuits upon the same pair of wires, as shown in Fig. 4

The transmitters were of the microphone type inserted in the armature circuit of the dynamo; provision for cooling was found to be unnecessary, especially when the transmitter was inserted in the line circuit instead of in the armature circuit of the dynamo. The telephone receivers were those regularly furnished for wireless telephony, ranging in resistance from 2,000 to 8,000 ohms.

The phenomena of resonance were very pronounced and highly consistent, since there is here a definite circuit free from the disturbances and variations inherent in radio-telegraphy and telephony.

Articulation tests, including music, numerals and other difficult combinations, gave satisfactory results, with no interference whatever between the two sides of the circuit. By holding one telephone receiver to one ear and the other receiver to the other ear the receiving operator could hear two entirely different conversations simultaneously over the same pair of wires.

A circuit was also made up with high-frequency apparatus inserted directly in the line in series. This gave apparently as good results as the bridging arrangement of the circuit.

Duplex-Diplex Telegraphy.

Having described in detail the experiments for obtaining the simultaneous transmission of two telephonic messages over a single circuit, it will be apparent that the problem of transmitting two telegraphic messages over the same circuit may be solved by methods and apparatus, as far as the high-frequency side of the circuit is concerned, which are practically identical with those described above.

In this connection the metallic circuit referred to was equipped with a standard Morse set for manual operation, and upon this circuit was superimposed an equipment for transmitting in one direction telegraphic messages by means of sustained high-frequency oscillations, employing the telephone as the means for receiving the signals.

Although little mention of telegraphy by high-frequency electric waves has been made thus far, as a matter of fact, it was found convenient during the experiments upon telephony actually to employ telegraphy as a quick and ready means of determining resonance between the circuits in each particular case. When any particular arrangement was being employed the first steps were invariably to send simple Morse signals over the circuit until the operator at the distant end of the line reported maximum loudness in the receiving telephone, which indicated that the terminal apparatus with the line circuit was properly tuned. This being accomplished it was necessary only to throw a switch, to substitute for the automatic interrupter and telegraph key the telephone transmitter, and the experiments could then proceed on telephony without any material change being made at the receiving station. Telephony and telegraphy thus proceeded hand in hand as a mere matter of convenience, and one of the practical advantages in the use of electric waves for transmitting intelligence is that the whole set-up of apparatus is practically the same for each and they can be used interchangeably over the same circuit.

Since the standard telegraph circuits of the world use an earth return, this same equipment was arranged to operate on one of the wires of the twisted-pair in the telephone cable as such a circuit with earth connections at each end, and its operations was equally successful.

Since it is a well-known characteristic of high-frequency apparatus used in tuned circuits that there shall be no iron involved in the circuit, it is evident that in cases where such a high-frequency current is to be superimposed upon a line comprising way-stations, where line relays are inserted directly in the circuit, it will be necessary and sufficient to shunt such way-stations by condensers of the order of magnitude of thousandths of a microfarad. Such condensers offer a comparatively free path for the high-frequency electric waves, but interpose a practical barrier to the Morse frequencies.

Since a portion of the telegraph lines now used is still composed of iron wires, it would be expected that electric waves would be propagated over such wires less efficiently than over copper wires, although it is well known that electric waves penetrate only about one-thirteenth as deeply into soft iron for a given frequency as into copper, but this is modified by the fact that the iron in telegraph wires is not soft iron and in addition is galvanised.

Measurements of Electric Waves.

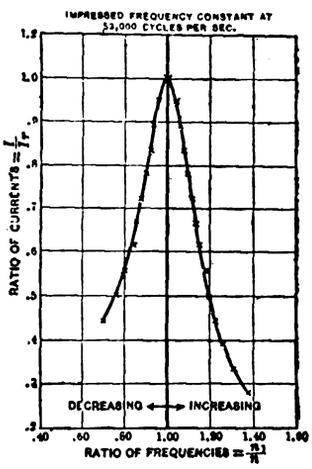
In order to understand more fully the conditions for the successful transmission of electric waves along commercial telephone cable conductors, a preliminary study of this particular line was made, and the engineering data obtained are submitted by the author.

Typical resonance curves were constructed, first with the line open at the receiving end, and, second, with the line short-circuited at the receiving end, after which the modifications introduced by the presence of certain terminal apparatus were briefly investigated. These are shown in the Paper for four frequencies between 95,000 and 36,500 cycles per second.

In order to interpret the curves from an engineering point of view, it is more valuable to plot them as selectivity curves, in which the line current is plotted as a function of the frequency. This is done in Fig. 5 for the case of $n=53{,}000$. It appears from an inspection of this curve that it is not symmetrical with respect to the ordinate

Digitized by Google

corresponding to resonance. The slope of the curve is steeper for increasing frequencies than for decreasing frequencies. A curve of this kind makes it possible to predict that terminal apparatus could be inserted in this line at the receiving end, provided it was in the nature of ohmic resistance, and that there would be no interference between several of such instruments operated at different frequencies, provided the interval between the frequencies of each of the different receiving sets was greater than 44 per cent., and that each receiving apparatus was not rendered inoperative by the presence of a stray current of 50 per cent. of its normal operating value. It should be remembered that this interpretation is from conditions controllable at the transmitting end only, and provides for no selective tuning whatever of the apparatus at the receiving end. In other words the curve given shows the selectivity of the line itself.



I_r = Line current at resonance.
I = Line current.
n = Frequency at resonance.
n_1 = Frequency of line circuit tuned to given dissonance.

FIG. 5.—SELECTIVITY CURVE OF TELEPHONE CABLE LINE, RECEIVING END SHORT-CIRCUITED.

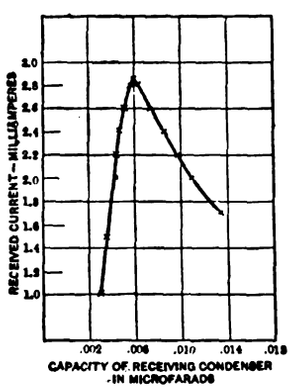


FIG. 6. — RESONANCE CURVE AT RECEIVING END OF TELEPHONE CABLE LINE. TRANSMITTING CURRENT CONSTANT AT 200 MILLIAMPERES AND AT 40,000 CYCLES.

For the range of frequencies involved in these experiments the values of the standard variable air condensers and variometers which are at present employed in wireless telegraph practice could better be made of larger electrical dimensions in order to be better adapted to the frequencies here considered.

The effects of introducing tuning elements across the line at the receiving end are shown in Fig. 6. At the transmitting end of the line the current and frequency were kept constant throughout, and at the receiving end of the line only the capacity element of the tuning apparatus was varied, which caused a rise and fall of the received current, as shown in Fig. 6.

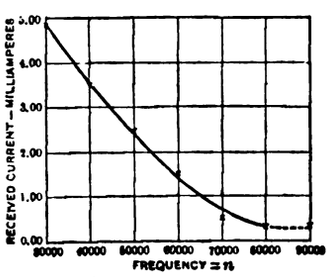

FIG. 7.—ATTENUATION-FREQUENCY CURVE AT RECEIVING END OF TELEPHONE CABLE LINE, SHORT-CIRCUITED THROUGH DUDDELL THERMO-AMMETER OF 17·1 OHMS.

To determine quantitatively the influence of variation of frequency upon the attenuation of the current transmitted over this telephone line the curve shown in Fig. 7 was obtained. In this experiment the transmitting current was kept constant at 240 milliamperes, the only thing varied being the frequency of the alternator.

The author sums up as follows: The foregoing experiments indicate that either the existing wire system, or additional wires for the purpose, may be utilised for the efficient transmission of telephonic and telegraphic messages, and the former without interfering with the existing telephone traffic on these wires. The fact that each of the circuits created by the use of superimposed high-frequency methods is both a telephone and a telegraph circuit interchangeably makes it possible to offer to the public a new type of service, which, it is believed, will offer many advantages to the commercial world. This type of circuit should be particularly applicable to Press Association service, railroad service and leased-wire service of all kinds.

The experiments described should not be interpreted as in any way indicating limitations to radio-telegraphy and telephony in the future, for their present rapid development gives justification for great prospect for the future. It is rather considered that the whole system of intercommunication, including both wire methods and wireless methods, will grow apace, and as each advance is made in either of these it will create new demands and standards for still further development.

Accustomed to the methods of transmitting energy for power purposes by means of wire, it is a matter of wonder that enough energy can be delivered at a receiving antenna from a transmitting point thousands of miles distant to operate successfully receiving devices. The value of a metallic wire guide for the energy of the electric waves is strikingly shown in the above experiments, and it furnishes an efficient directive wireless system which confines the ether disturbances to closely bounded regions and thus offers a ready solution of the serious problems of interferences between messages which of necessity have to be met in wireless operations through space.

The distortion of speech, which is an inherent feature of telephony over wires, should be much less, if not practically absent, when we more and more withdraw the phenomena from the metal of the wire and confine them to a longitudinal strip of the ether which forms the region between the two wires of a metallic circuit. The ohmic resistance of the wire as shown can be made to play a comparatively unimportant part in the transmission of speech and the more the phenomena are of the ether, instead of metallic conduction, the more perfectly will the modified electric waves, which are the vehicle for transmitting the speech, be delivered at the receiving point without distortion.

It has been shown that the phenomena of resonance exhibit very striking and orderly results when applied to electric waves propagated by means of wires. By utilising this principle it has been shown that the receiving current at the end of the line may be built up and amplified many times over what it would be with untuned circuits. The tuned electrical circuit at the receiving end readily admits electromagnetic waves of a certain definite frequency, and bars from entrance electromagnetic waves of other frequencies. This permits the possibility of utilising a single circuit for multiplex telephony and telegraphy.

ELECTRICITY IN MINES: AVOIDANCE OF ACCIDENTS.

We give below a short account of the adjourned discussion at a joint meeting of the Scottish Branch of the National Association of Colliery Managers and the West of Scotland branch of the Association of Mining Electrical Engineers, on the Paper contributed a few months ago by Mr. Robert Nelson, H.M. Electrical Inspector of Mines. An abstract of this Paper appeared in THE ELECTRICIAN, April 7, 1911.

Mr. C. A. ATCHLEY (Kilmacolm), in reopening the discussion, said he wished that on a Paper of this kind they could elicit more freely than they had hitherto done the views of colliery managers who were actually using electric plant, because there was no doubt that the question of accidents and loss of life was becoming very serious indeed. The fact of the matter was that electrical engineers needed all the light and leading they could get, especially from the practical standpoint, from those who had electrical plant in operation. For the present he proposed only to deal with one single point—namely, the vexed question of the use of armoured cables. In regard to the proposal of the Home Office to enforce the use of armoured cables, he felt that in the majority of instances, particularly in regard to new works, armoured cables were safer than unarmoured cables. He had the fear, however—and he believed others felt the same way—that in discarding unarmoured cables straight away, and adopting armoured cables universally, they were going much too fast. The point that appealed most strongly to him was that the class of man who was quite able to superintend and maintain the insulation of an unarmoured cable might not, except after a considerable period of training, be equal to the responsibility of maintaining an armoured cable system.

Mr. A. B. MUIRHEAD thought that the principal points involved in the present Paper were those in relation to earthing and the number of fatal accidents. Candidly, he was bound to admit that he was not satisfied in his own mind that the earthing of everything was going to result in safety. There was just the chance that they would get to that stage—since everything electrical in the pits was to be connected up through armoured cables and carefully earthed—when the standard of insulation would begin to deteriorate, and they would rapidly reach the stage when they would be worse off than they were to-day. He

Digitized by Google

whole contention frankly was that the question of insulation was not receiving the same measure of attention as that of earthing.

Mr. McVIE, speaking as a colliery manager, said it was a pity that the author of the Paper was not present, otherwise he would have asked him to reply to the very straightforward observations which Mr. Muirhead had made. Colliery managers were in somewhat of a difficulty, because they had the Home Office definitely laying down rules that everything was to be earthed, while, on the other hand, they had acknowledged experts like Mr. Muirhead and others declaring that Mr. Nelson and the Home Office were practically wrong. It was his feeling that at the last joint meeting Mr. Alexander Anderson, President of the West of Scotland Branch of the Association of Mining Electrical Engineers, had raised some very important points, and it did not appear to the speaker that the replies which he got from Mr. Nelson were at all satisfactory.

Mr. ALEXANDER ANDERSON (chairman) said he had it from quite an authoritative source that Mr. Nelson intended replying to the discussion when it was concluded.

Mr. GEORGE L. KERR (secretary of the Scottish branch of the National Association of Colliery Managers) said he would be glad if electrical experts would give their opinion as to whether earthing locally or at one central point on the surface was preferable. Then there was the further point as to whether earthing was preferably effected outside rather than inside the cable. He knew of one fatal accident where the victim actually lost his life due to the earth wire. In conclusion, he desired to remark that 80 per cent. of the accidents he had investigated in the course of his professional duties were on three-phase systems, and less than 20 per cent. on direct-current installations.

Mr. ALEXANDER ANDERSON remarked that the point raised by Mr. Kerr as to whether the earth wire should be outside or inside the cable was one which was giving electrical engineers some little concern at the present time. At one period he might tell them quite frankly that he favoured the idea of the earth wire being inside. Now, however, he was absolutely opposed to that arrangement, if it was possible to earth on the outside. He believed that if an earthed system was adopted they could not have too many earthing points. Further, he held strongly to the belief that, in the majority of cases, the surface should be one of these points. With regard to the question as to whether three-phase or direct current was the more dangerous system, he had no hesitation in giving a verdict against three phase. No doubt the three-phase was an admirable system, but so far as relative safety was concerned there was no doubt in his mind as to which he would prefer.

The discussion was then adjourned to a future meeting.

REPORT OF THE BRITISH ASSOCIATION COMMITTEE ON PRACTICAL STANDARDS FOR ELECTRICAL MEASUREMENTS.*

The Committee have to regret the death since the last meeting of the Association of Dr. G. Johnstone Stoney, F.R.S. He had been a member since 1861, and up to a few years since continued his active interest in the work. In its earlier stages his skill in definition and admirable choice of nomenclature had proved invaluable to the Committee. The collected reports which are to be issued shortly will indicate how large a share in the establishment of the C.G.S. system of units is due to him.

Republication of Reports.—The republication of the reports is not yet completed, but this should be done within the present year. The proofs of the reports from 1862 to 1883 have been finally revised and the remaining proofs will soon be ready.

Current Apparatus.—The progress made has been satisfactory. Preliminary experiments have shown that the apparatus is uninfluenced by changes in the earth's magnetic field and that the thermal E.M.Fs at the brushes on the two discs very nearly balance. With the form of brush in use at present there are sudden changes in the difference of the thermal E.M.Fs amounting to 2×10^{-7} volt, and it will be difficult entirely to eliminate these. With other forms of brush, *e.g.*, those made of gauze, the difference was often 1,000 times as great. It was this difficulty which led Lord Rayleigh in 1884 to amalgamate the edge of the disc, and as a further improvement Prof. Viriamu Jones and Prof. Ayrton used mercury jets instead of brushes. Since in the present apparatus the changes are only 1 in 100 of the difference of potential produced in one arrangement of brushes and less for a second arrangement, it is hoped that mercury contacts will not be necessary. Further experiments will be made in order to obtain greater perfection if such is possible.

Resistance Standards.—The construction of new mercury standards of resistance in accordance with the specification of the London Conference is being proceeded with, and some of the standards will be completed this year. Similar work is in progress in France, in Germany, in Austria, and in the United States. In the latter country four standards have had all of their constants determined, and the resistance unit so obtained is in very close agreement with that obtained from the old National Physical Laboratory standards.

In the Committee's Report for 1908 it was shown that many manganin resistance coils—some of which were purchased by the Committee in 1895—were very changeable in resistance, and in consequence frequent comparison with mercury standards was necessary. In 1908 it was shown at the Bureau of Standards, and confirmed at the National Physical Laboratory and at the Reichsanstalt, that these changes were largely due to the effect of moisture on the shellac covering the wire. To eliminate this source of trouble, many of the coils were hermetically sealed in 1909, and it is satisfactory to record that they are now much more constant. The importance of this hermetical sealing is so great when manganin resistances are to be sent to such places as cable stations in the tropics that the attention of instrument manufacturers is drawn to the matter. Standard coils are readily sealed and boxes of coils may be sealed in metal cases. The following figures for standard coils of manganin show the advantage of hermetical sealing :—

Nominal value . . .		100 ohms.		1,000 ohms	10,000 ohms
		No. 2450.	No. 740.	No. 2449.	No. 2448.
Open coils	Oct.: 1903	99·995$_9$	1,000·15$_2$	1,000·01$_2$	10,000·2$_4$
	1904	100·000$_2$	0·17$_2$	0·24$_4$	2·4$_0$
	1905	0·000$_8$	0·21$_8$	0·49$_4$	3·5$_7$
	1906	0·009$_2$	0·24$_8$	0·66$_8$	3·8$_2$
	1907	0·013$_2$	0·26$_6$	0·81$_4$	3·7$_4$
	1908	0·028$_8$	0·30$_2$	1·13$_0$	3·8$_5$
Hermetically sealed in paraffin oil	June 1909	0·036$_9$	0·36$_5$	1·01$_6$	5·5$_3$
	1910	0·038$_4$	0·35$_7$	1·07$_5$	5·5$_5$
	1911	0·039$_9$	0·35$_9$	1·06$_9$	5·6$_1$

It will be noted that the changes during the last three years are very small.

Silver Voltameter and Standard Cell.—Although the actions which take place when a current passes through a solution of silver nitrate as in a silver voltameter are now well understood, the effects of septa—such as silk, filter paper, and porous porcelain—are by no means clear, and experiments have, therefore, been made to decide whether any septum at all should be used in a voltameter. Such experiments were suggested at the Washington meeting in 1910. The results of the experiments made at the National Physical Laboratory indicate that a septum of any kind is usually a source of trouble, and may produce secondary reactions during the electrolysis which affect the weight of the silver deposit. Fortunately, voltameters have been designed which render a septum unnecessary, and these may be useful not only in precise current measurements with the silver voltameter, but for the deposition of metals other than silver.

The reproducibility and constancy of the Weston normal cell are still being carefully examined. The chief anomaly is the hysteresis effect mentioned in last year's report: for this effect we have no explanation although one is much needed, as probably it would enable cells to be made so as to remain even more constant in E.M.F. than at present. It is necessary to point out that while the effect is called a hysteresis one, the E.M.F. does not lag behind the temperature. Briefly put, with ascending temperatures the E.M.F. changes in close agreement with the temperature—E.M.F. formula, but with descending temperatures the E.M.F. changes too rapidly, corresponding to values at temperatures lower than the temperature of the cell, by from 3 deg. to 15 deg.

The Committee had hoped to have made this their last report, but in view of the fact that the republication is not complete they ask for reappointment, with Lord Rayleigh as chairman and Dr. R. T. Glazebrook as secretary.

Utility of the "Dead Man's Handle."—According to the "Electric Railway Journal," on July 14th, as a train on the New York Subway was proceeding at full speed, the motorman looked out of the side door of his compartment, and in so doing his head struck a signal post. The man was killed by the blow and his body was thrown out of the compartment. This freed the stop in the motor controller handle, so that it rose automatically, cutting off the current and applying the brakes, and pulled up the train in three cars' length.

* Report presented at Portsmouth. The Committee consists of Lord Rayleigh (chairman), Dr. R. T. Glazebrook (secretary), Profs. J. Perry, W. G. Adams and G. Carey Foster, Sir Oliver Lodge, Dr. A. Muirhead, Mr. W. H. Preece, Profs. A. Schuster, J. A. Fleming and Sir J. J. Thomson, Mr. W. N. Shaw, Dr. J. T. Bottomley, Rev. T. C. Fitzpatrick, Prof. S. P. Thompson, Mr. J. Rennie, Principal E. H. Griffiths, Sir Arthur Rücker, Prof. H. L. Callendar and Messrs. G. Matthey, A. P. Trotter, Prof. T. Mather, and Mr. F. E. Smith.

Vols. I to LXVI. can now be supplied. Price on application.

"THE ELECTRICIAN" SERIES OF STANDARD ELECTRICAL BOOKS

can be obtained of all Booksellers at Home, in the Colonies, and Abroad.

'THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. Published annually in February, corrected to mid-February. Established 1882. A very valuable advertising medium, covering the entire Industry. SUBSCRIPTION Price (which is received *in advance* up to Jan. 31st in each year for the next following edition) 8s 6d. nett, postage 9d. extra. Published price 15s. nett, postage 9d. extra. Postage to British Colonies, 2s; Europe, 2s; U.S.A., 3s. 6d.; other countries, 2s. 6d. *Digest of Contents of the 1911 Edition sent free on application.*

THE PRACTICAL WIRELESS SLIDE RULE. By Dr. H. R. Belcher-Hickman. Price 2s. 6d. nett. *Reduction on quantity.*

LIVINGSTONE'S DIAGRAM FOR THE EASY CALCULATION OF SHAFT AND BEAM DEFLECTIONS. By R. Livingstone. 2s. 6d. nett. By post in tube, 2s. 10d.

"THE ELECTRICIAN" PRIMERS (81 Primers in all, and a GLOSSARY). Single Primers 3d. each post free. *New and Enlarged Edition in One Complete Vol. or Three Separate Vols.* FULL PROSPECTUS FREE.

ELECTRIC TRACTION ON RAILWAYS. By Philip Dawson. Price 25s. nett. *Prospectus free.*

ALTERNATING-CURRENT MOTORS. By Dr. Rudolf Goldschmidt. Price 6s. 6d.

THE SHOT-FIRER'S GUIDE: A Practical Manual on Blasting and the Prevention of Blasting Accidents in Mines, Quarries, &c. By W. Maurice. Price 3s. 6d. nett.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. Wilkinson, M.I.E.E. *New Edition.* Now ready. Price 15s. nett.

ELECTRIC BLASTING APPARATUS AND EXPLOSIVES: With Special Reference to Colliery Practice. By W. Maurice. Price 8s. 6d. nett.

THE ELECTRIC FURNACE IN IRON AND STEEL PRODUCTION. By John B. C. Kershaw, F.I.C. Price 3s. 6d. nett.

BRAKES FOR TRAMWAY CARS. By H. M. Sayers. Price 3s. 6d. nett.

THE MECHANICAL DESIGN AND CONSTRUCTION OF COMMUTATORS. By R. Livingstone. Price 6s. nett.

THE ALTERNATE-CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. [abroad 13s.

VOL. I.—Price 12s. 6d. post free, abroad 13s. VOL. II.—Price 12s. 6d. post free, abroad 13s.

HANDBOOK OF THE ELECTRICAL LABORATORY AND TESTING ROOM. Very fully illustrated. By Dr. J. A. Fleming. Vol. I., 12s. 6d. nett. Vol. II., 14s. nett.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. Fleming. 6s. nett.

ELECTRICAL LABORATORY NOTES AND FORMS. Arranged by Dr. J. A. Fleming, M.A., F.R.S. Single copies 4d. nett, or in dozens at 3s. 6d. nett. Complete Sets of 50 Notes and Forms, 12s. 6d. nett, or in strong portfolio, 14s. nett; or bound in strong cloth, 15s. nett. Spare Copies of Tabular Sheets, 1s. per dozen. Portfolios, 1s. 6d. each. Sectional paper, 1s. per dozen sheets. *Complete Prospectus post free on request.*

ELECTRICITY METERS: THEIR CONSTRUCTION AND MANAGEMENT. By C. H. W. Gerhardi. Profusely illustrated. Price 9s. nett.

ELECTRICITY IN HORTICULTURE. By Prof. S. Lemstrom. Illustrated. 3s. 6d nett.

RADIO-ACTIVITY: AN ELEMENTARY TREATISE, FROM THE STANDPOINT OF THE DISINTEGRATION THEORY. By Fredk. Soddy, M.A. Fully illustrated. Price 6s. 6d. nett.

ELECTROMAGNETIC THEORY. By Oliver Heaviside. Vol. I. Price 12s. 6d. Vol. II. Price 12s. 6d. *Vol. III. in the press.*

MOTIVE POWER AND GEARING FOR ELECTRICAL MACHINERY. By E. Tremlett Carter, C.E., M.I.E.E. Revised by G. Thomas-Davies, A.M.I.E.E., F.C.S. Price 12s. 6d. nett.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. Ewing, B.Sc., F.R.S., F.R.S.E. Price 10s. 6d.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. Kennelly and H. D. Wilkinson, M.I.E.E. Price 6s. 6d.

ELECTRIC MOTIVE POWER. By Albion T. Snell. Price 10s. 6d. nett.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. Geipel and H. M. Kilgour. Price 7s. 6d. nett.

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. Elton Young. Price 10s. 6d.

STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By H. K. C. Fisher and J. C. H. Darby. Price 7s. 6d. nett.

SIGNALLING ACROSS SPACE WITHOUT WIRES: THE WORK OF HERTZ AND HIS SUCCESSORS. With new Chapter on Tuning. By Dr. Sir Oliver J. Lodge. Price 5s. nett.

THE ART OF ELECTROLYTIC SEPARATION OF METALS. By Dr. G. Gore, LL.D., F.R.S.

ELECTRO-CHEMISTRY. By Dr. George Gore. Price 2s. [Price 10s. 6d.

BEGINNER'S MANUAL OF SUBMARINE CABLE TESTING AND WORKING. By G. M. Baines. Price 7s. 6d. nett.

CARBON MAKING FOR ALL ELECTRICAL PURPOSES. By Francis Jehl. Price 10s. 6d.

"THE ELECTRICIAN" WIREMAN'S POCKET BOOK. Price 5s. nett.

"THE ELECTRICIAN" HANDY WIRE TABLES FOR THE POCKET. By P. B. Down, Wh.Ex., A.M.I.Mech.E. Price 2s. 6d. nett.

THE RATING OF ELECTRIC LIGHTING, ELECTRIC TRAMWAY, AND SIMILAR UNDERTAKINGS. By W. G. Bond, M.I.E.E. Price 2s. 6d. nett.

DRUM ARMATURE WINDING AND COMMUTATORS. By F. M. Weymouth. 7s. 6d.

PRIMARY BATTERIES: THEIR CONSTRUCTION AND MANUFACTURE. By W. R. Cooper. Price 10s. 6d. nett.

SECONDARY BATTERIES: THEIR CONSTRUCTION AND MANUFACTURE. By E. J. Wade.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. Price 1s. 6d. [Price 10s. 6d. nett.

THE LOCALISATION OF FAULTS IN ELECTRIC LIGHT CABLES. By F. C. Raphael. 7s. 6d.

THE STEAM-ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. Beaumont, M.I.C.E., M.I.M.E., &c. Price 6s. nett.

THE ELECTRIC ARC. By Mrs. Ayrton. M.I.E.E. Price 12s. 6d.

TRAMWAY TRACTIVE EFFORT AND POWER DIAGRAM. By Arnold G. Hansard, B.A., A.M.I.E.E. Price 4s. 6d. nett; in Tube, 5s.

THE BRITISH POST OFFICE TELEPHONE SERVICE. Fully illustrated. Price 3s. 6d. nett.

INTERNATIONAL TELEGRAPH CONVENTION AND SERVICE REGULATIONS. Price 6s. nett. (LISBON REVISION, 1908.)

BOILER FEED WATER. By F. W. Anderson. Price 6s. nett.

(PRELIMINARY) WIRELESS TELEGRAPH CONFERENCE (BERLIN, 1903), PROCEEDINGS AT. Price 8s. 6d. nett.

INTERNATIONAL WIRELESS TELEGRAPH CONVENTION AND SERVICE REGULATIONS (BERLIN, 1906). With complete report of Proceedings. Price 21s. nett.

THE TWO-TONE VIBRATING TRANSMITTER AND CABLE INDUCTIVE SIGNALLING. By Edward Raymond-Barker. Price 1s. nett and post free. [Price 3s. nett.

THE CLASSIFICATION OF ALTERNATE-CURRENT MOTORS. By V. A. A. Fynn, M.I.E.E.

ELECTRIC CRANES: THEIR DESIGN, CONSTRUCTION AND APPLICATION. By H. H. Broughton. Being Vol. I. of a Complete Manual of Lifting and Hauling Machinery. *Ready in September*, price 25s. nett.

AITKEN'S MANUAL OF THE TELEPHONE. By W. Aitken, M.I.E.E. *Ready in September.*

ELECTRIC MAINS AND DISTRIBUTING SYSTEMS. By J. R. Dick, B.Sc., and F. Fernie, A.M.Inst.C.E. *Ready in September.*

ELECTRICAL MANUAL FOR MINING ENGINEERS. By H. J. S. Heather, M.I.E.E. *Ready in December.* [*In Preparation.*

THE MECHANICAL DESIGN AND CONSTRUCTION OF GENERATORS. By R. Livingstone.

STUDIES IN LIGHT PRODUCTION. By R. A. Houston, M.A., Ph.D., D.Sc. *In Preparation.*

LIGHT, RADIATION AND ILLUMINATION. From the German of Paul Hogner, by Justus Eck. *In Preparation.*

WIREMAN'S POCKET BOOK AND ELECTRICAL CONTRACTOR'S HANDBOOK. Compiled by A. W. Robinson and W. E. Warrilow. Price 5s. nett. *Ready in September-October.*

AMATEUR WIRELESS TELEGRAPH DESIGNS. By "Alfrec." Very fully illustrated. *Ready in September.* Price 1s. 6d. nett.

The Electrician.

The Oldest Electrical Journal (established as a weekly Journal, 1861-1878)

Published every Friday, Price Sixpence; Post Free, Sixpence-Halfpenny.

Editorial, Publishing and Printing Offices,

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON

(ONLY ADDRESS.)

"THE ELECTRICIAN" INDUSTRIAL SUPPLEMENT.

With "THE ELECTRICIAN" for Sept. 14, 1906, was issued the first of a series of "Industrial Supplements," to be published from time to time with "THE ELECTRICIAN." The fifty-third issue of the Supplement published (Gratis) with the number of "THE ELECTRICIAN" for September 23, 1910, was the last of the monthly issues. "THE COMMERCIAL AND INDUSTRIAL SUPPLEMENT" to "THE ELECTRICIAN" is now issued weekly (Gratis). It will be found towards the end of the present issue.

NOW READY.

Vol. LXVI. of "THE ELECTRICIAN." Bound in Publisher's covers. Price 17s. 6d. Postage U.K. 1s. extra, abroad 2s. 6d.

Cases for binding Vol. LXVI. are now ready, price 2s.; post free, 2s. 3d.

THE FIXATION OF NITROGEN.

The advance of the electrical fixation of nitrogen as an industry has been one of the most remarkable events of the last few years. It is not so very long ago that Sir WILLIAM CROOKES called attention to the extreme importance of obtaining a greater agricultural output from the soil than is at present customary, and that this could only be done by supplying the soil with greater quantities of manure. This in itself, was a fairly self-evident statement, but the argument with which it was met was that the quantity of manure available was insufficient to carry out such a policy. Sir WILLIAM pointed out that the nitrogen of the air, if it could be brought into service sufficiently cheaply, provided a solution of the difficulty. No commercial process was then available, but before so very long the Birkeland-Eyde process came into existence, and this has been followed by two or three others, so that at the present time the power so utilised is running into very large figures.

Although nitrogen is remarkable in chemistry for its apparent inertness, it plays a most important part in Nature. In plant life it is indispensable, and if the soil does not contain a sufficient quantity of nitrogen in some form or another the results are poor. As a manure it is generally applied in the form of a nitrate or a salt of ammonium. In the Birkeland-Eyde process the product takes the form of calcium nitrate; whereas in the Frank-Caro process the product is cyanamide. These products differ somewhat in their properties and in the way in which they are used, but it appears that they may be very advantageously mixed together, the applica-

Digitized by Google

a manure being then more easy than when these materials are used separately.

Another field in which nitrogen is important is that of explosives, though the quantity required in this direction is small compared with that which could be used profitably in agriculture. Most of our explosives depend in their production upon nitric acid in some form or another.

As the deposits of Chile saltpetre become exhausted, the electrical production of nitrates will assume enormous proportions. It is only natural therefore that the electrical engineer should look upon this growing industry with covetous eyes and wish to see some development of it in this country. This reason is sufficient to account for the Paper read by Mr. KILBURN SCOTT before the British Association last week. As will be seen by the abstract which appears elsewhere, Mr. SCOTT takes up the subject from two points of view—the agricultural and the explosive. The great difficulty in fostering an industry of this kind in Great Britain is that extremely cheap electrical power is a *sine qua non*, the cost of power being the most important item in the total cost of production. The suggestion is put forward that the manufacture of explosives should not be treated commercially, for the reason that in the event of war this country might find itself placed in a very awkward predicament if the supply of nitrate were cut off. In order that we might manufacture explosives without being dependent upon outside supplies of nitrate the Government might erect a factory for the production of nitric acid from atmospheric nitrogen by one of the electrical processes now available. Although it is to be hoped that this country will be saved from the horrors of war indefinitely, there is no better means of preventing war than by preparing for it, and from that point of view there is something to be said in favour of Government action of this kind. We must confess that we doubt very much whether any Government will act in this direction, though possibly a subsidy might be given to some private enterprise on condition that this method of manufacture might be available for the Government in case of need.

At the conclusion of his Paper Mr. SCOTT discusses the question whether electrical power might not be generated sufficiently cheaply in this country to compete with Norway's water power. We fear that this cannot be done. The capital cost of water power in certain parts of Norway is extraordinarily low, and consequently the price per kilowatt-hour for which electrical energy can be obtained is something like one-twentieth of a penny. Undoubtedly the capital cost of steam stations has been very much reduced during the last few years, and a figure of £10 per kilowatt installed is now quite possible. With waste heat stations the cost may be still lower, but there seems to be great difficulty in getting down to the desired figure, even when the difference in freight is taken into account. It appears to us that the most feasible means is for some of the power companies to supply energy on the "restricted hour" basis. From the point of view of uniformity in electro-chemical manufacture this method is at a disadvantage, but possibly the lowness in cost might be a sufficient offset to enable intermittent working to be adopted. It may also, perhaps, be worth asking if there is not sufficient water power available in the British Isles to warrant the starting of a factory with a hydro-electric plant. It would not be possible to rival the factories now to be found in Norway, but the plant might be sufficiently large to be commercially successful and to be of use to the Government in time of need.

REVIEWS.

(Copies of the undermentioned works can be had from THE ELECTRICIAN Office, post free, on receipt of published price, adding 3d. for books published under 2s. Add 10 per cent. for abroad or for foreign books.)

Mesures Electriques Industrielles. By J. A MONTPELLIER and M. ALIMET. (Paris; H. Dunod and E. Pinet.) Pp. 468. 18fr.

This book, forming the third volume of a series intended as a practical guide to industrial measurements, covers more or less familiar ground in an orderly manner and with the clearness and conciseness of statement one has come to associate with French scientific text-books. Commencing with two chapters of an introductory character in which units, definitions, classification of instruments, attainable accuracy, sources of error, and classification of methods are successively dealt with, the authors pass on to a consideration of electrostatic, electromagnetic, dynamometric, induction, and thermal instruments in the order named, this section of the book closing with a chapter on what are conveniently classed as accessories, viz., resistances, shunts, and instrument transformers. The remaining space, representing a little over one-half the book, is devoted to methods of measuring resistance, E.M.F., current, quantity, capacity, power, energy and inductance, each of which gets a chapter to itself. The penultimate chapter discusses special methods in alternating-current measurement such as determination of wave-form, measurement of frequency, and measurement of phase difference; and the last chapter contains a condensed account of electricity meters with instructions for testing.

The book is mainly descriptive, theory being kept well in the background, although enough is usually given to make clear the "how" and the "why" of the particular instrument or method under consideration. More than occasionally, however, the reader's powers of faith are largely drawn upon, as, for instance, in an otherwise excellent chapter on the measurement of three-phase power, where the reader is asked to accept without any attempt at proof the bald statement that the sum of the readings of two wattmeters arranged in a certain way gives the true power.

Inequality of treatment strikes one forcibly in several places. The authors are certainly to be commended for introducing quite a full account of such a recent instrument as the Drysdale alternating-current potentiometer. On the other hand the measurement of insulation resistance and of dielectric strength hardly receive their fair share of treatment; the latter subject being dismissed in nineteen lines of text and a few tables without allusion to the half-dozen or so different conditions which affect the results. Again, valuable space to the extent of two pages is taken up by a table of doubled square roots for use with Kelvin's balance; whereas the subject of the arithmetical analysis of alternating-current wave-forms is dismissed with the curt remark that it "does not come within the scope of this book," a reference, however, being given to another work (by the same publishers) where the necessary information may be found.

But references are not much in evidence, a paucity which undoubtedly constitutes a serious defect in a work of this kind. Seeking, as it does, to cover within a limited space a wide and still widening field, careful selection is of course necessary, and a few typical examples of apparatus and methods can alone be dealt with adequately. Therefore it would not be surprising to find, for example, that electrostatic ohmmeters, vibration galvanometers, and several well-known forms of alternating-current wave tracers, like the instruments of

Digitized by Google

Duddell, Francke, Rosa, and Siemens and Halske, are not discussed at length; but to find them omitted altogether is more than one is prepared for. Opinions may differ as to what particular types should receive preference, and doubtless the authors are justified in giving that preference to the home-grown article, but surely they might at least have mentioned and given references to the above-named instruments instead of ignoring them entirely. Much may be forgiven a book of this class if only a full list of references is provided; at the worst, it still serves as a directory or inventory of ways and means, and as such fulfils a most useful function however meagre or unsatisfactory its text may be.

Needless to say there is no alphabetical index, the authors apparently imagining that a distended table of chapter contents placed at the end of the book is a satisfactory equivalent.

R. BEATTIE.

The Development of the Telephone in Europe. By H. LAWS WEBB. With an Introduction by H. COX. (London: *Electrical Press, Ltd.*) Pp. 78. 1s. nett.

What is in many respects an interesting contribution to the literature of telephonic development is marred by exaggerations. Mr. Webb holds the State responsible for all the errors of policy, management and engineering in countries where the telephones are State controlled. The *motif* of the book is the taking over by the Government of the National Telephone Co.'s system—the term of years for which the licence was granted to that Company expiring at the end of this year.

The main arguments against State control are:—The Government have not made the telegraphs pay, therefore the telephone purchase must result in loss also. Government officials having assured positions cannot be expected to be conscientious and carry out in an energetic and business-like manner the highly technical business of telephony. Money will not be readily obtainable to carry out extensions and reconstructions necessary in a rapidly developing business in which plant so frequently needs replacing.

The book deals with "The Rise and Evolution of the Telephone Service" (Chapters I. and II.), "American and European Development Compared" (Chapter III.), "The Telephonic History of Great Britain," (Chapters IV., V. and VI.), "Some Reasons for Popular Prejudice Against the Telephone" (Chapter VII.), "The Essential Features of Telephone Policy" (Chapter VIII.), "Survey of Telephone Development on the Continent of Europe (Chapters IX. to XII.).

In the first paragraph the author compares the telephone development of the United States with the whole of Europe—one wealthy and highly developed State of 80 million people against a conglomeration of wealthy and poor States, many of them badly developed, with a population of 400 millions. This is done to show poor benighted Europe with 6·4 telephones per thousand against 87 in "God's Own Country." Why not take an area in America having 400 million people, or nations in Europe having 80 millions for comparison? The figures would still be bad enough, but the author wants to paint us as black as possible.

The author makes the statement that America is the only country where telephony has been developed, or is in process of being developed, to its utmost capacity, and that because there is no State control. This freedom may be one reason, but another is the competition of independent companies. These have had a far-reaching effect on telephone development in the United States. Up to the time they started, about 1896, the Bell system was comparatively small in numbers, not very good, and the rates very high. On the expiry of the Bell patents the "independents" started active competition, and in some of the Western states to-day their telephones equal in numbers those of the "Bell." They threatened the Eastern States also, but by introducing modern plant, and the message-rate system, the Bell Co. have prevented their making the same headway. The independent companies own to-day at least one-third of the total telephones in use. No greater argument could be cited in favour of competition in telephones than the splendid results attained in America, and, as Mr. Webb says in another part of his book, "If the municipal systems in this country had been better organised, and conducted more in accordance with the technical requirements of the telephone business, there might be a different story to tell."

In this country we have largely followed the lead of America, and therefore we are behind. We were two or three years late with the C.B. system; we followed, and less thoroughly, with the message-rate system, and similarly with the private branch exchange development.

There are many points in the book one would like to query, *e.g.*, "When the P.O. succeeds to the telephone service it will succeed to a congested plant, without proper facilities for expansion and without proper development studies to govern plans for future construction." Will this be so?

Has the limited tenure been entirely to blame for the comparatively slow introduction of the C.B. system? Mr. Webb states that New York introduced this system between 1898 and 1901. If London and other large cities had been similarly converted at the same time, practically the life of the switch-boards would have terminated with the licence.

Mr. Webb mentions a more cogent reason for slow development in another place, viz., the opposition of the local authorities and the want of powers, such as the Post Office possesses, to over-ride difficulties.

Mr. Webb thinks the terms of purchase harsh, and we sympathise with him when he says:—"The National Telephone Co., which has built up a great business under very difficult and discouraging conditions, and has organised and developed a great public service to a high pitch of scope and efficiency, is treated with discouraging harshness and parsimony." May the final result be otherwise.

The die is cast, and for good or evil we are to have State control—unless the belated suggestion of a central authority finds favour and support.

W. A.

Génératrices de Courants et Moteurs Electriques. By C. GUTTON. (Paris, 1911: H. Dunod et E. Pinat.) Pp. vi.+292. 9fr.

This book is one of those occupying a definite place between the elementary text book and works written by specialists on electrical machine design.

It is the outcome of lectures given at the Electrotechnical Institute of the University of Nancy by the author, to students intending to become electrical engineers, and within a moderate compass he has succeeded in developing a clear and connected argument covering practically the whole subject indicated by the title.

This has been done by concentrating attention on a broad comparative study of different types of machines to the exclusion of discussion on points of unessential detail. For instance, great elaboration in the treatment of the circle diagram of the induction motor has been avoided, while the analogies between it and the continuous-current shunt motor have been dwelt upon.

There are, however, a few matters on which more might have been said. On page 56 it would appear that the heating of a machine is the only limit to its output. No reference is made to limits sometimes imposed by sparking or excessive voltage drop. On the same page, the manner in which losses due to eddy currents and hysteresis are taken together would leave the reader ignorant of their different variation with speed. The chapter on commutator motors contains no reference to the use of high-resistance connections between commutator and armature winding, and in considering the Latour motor some mention should have been made of the work of Eichberg and Winter. The treatment of converting machinery is incomplete by the omission of any discussion of the motor converter.

On the other hand, the elaborate method of predetermining alternator regulation curves in which three coefficients are required might well have been omitted, in favour of Potier's ingenious adaptation of Rothert's and Behn-Eschenburg's constructions.

A valuable feature running through the whole book is the method adopted of separately constructing the magnetic field due to each winding of a machine when carrying current, and then investigating the result. This has led in the hands of the

Digitized by Google

author to a real presentment of working conditions. Although this method is not of great use in the derivation of numerical formulæ, yet, as the author truly remarks at the end of his preface, this has not been the object aimed at.

The book will well repay study both by teachers and students.

W. C. C.

STUDIES IN LIGHT PRODUCTION.*

BY R. A. HOUSTOUN, M.A., PH.D., D.SC.

(Lecturer in Physical Optics in the University of Glasgow.)

(*Continued from page 862.*)

Summary.—In these studies the author deals with the theory of light production, the scope being briefly indicated by the following contents: (1) The distribution of the energy in the spectrum and the measuring of efficiency. (2) The importance of "black body" radiation and the experimental realisation of the black body. Comparison of the energy curves of a black body and of platinum, and the variation of the position of maximum energy with temperature. (3) Mechanism of flame, and the temperature, energy and efficiency of flames. (4) The Welsbach mantle and selective radiation. (5) Radiation and efficiency of the carbon glow lamp. (6) Physical properties and temperature of the arc. (7) Temperature and energy curves of the Nernst glower. (8) Efficiency of the metal filament. (9) The mercury arc and its difficulties. (10) The light of the future and the possibility of obtaining "cold light."

No. 2.—The Black Body.

According to the modern view, light may be produced in two ways, by temperature radiation and by luminescence. If the source is emitting light merely as a result of being heated, and if it is not suffering any chemical change in the process, we have a case of temperature radiation. The electric glow lamp, the Nernst filament and the incandescent mantle belong to this class. Here the electrons which emit the light waves are caused to vibrate as a result of the motion of the molecule as a whole. If, on the other hand, light is produced, not as a result of heat, but as a result of electric energy being conveyed to the source, or as a result of chemical energy being liberated, we have luminescence. The aurora borealis, the vacuum tube, the light given off by phosphorus in the dark, are all cases of luminescence. In these cases the source is cold, and no kinetic energy is given to the atom or molecule as a whole.

Luminescence has not been studied much from the point of view of the energy curve, chiefly on account of experimental difficulties. Temperature radiation has been studied very fully and accounts of the principal facts have been given by Kayser, Day and Van Orstrand, and Waidner and Burgess. (Kayser's "Spectroscopie," Vol. II., Chapters I. and II. Arthur L. Day and C. E. Van Orstrand, "The Black Body and the Measurement of Extreme Temperatures," Astrophys. J., 19, p. 1, 1904. C. W. Waidner and G. K. Burgess, "Optical Pyrometry," Bull Bureau of Standards, p. 189, I., 1905.)

In 1859 Kirchhoff published the law that the ratio of the radiating power to the absorbing power of all bodies is the same and a function of the wave-length and the temperature. By the radiating power of a body is meant the quantity of heat radiated from unit area of its surface in unit time; by the absorbing power is meant that fraction of the energy incident on the surface which is absorbed by the body.

The law may be proved for one particular case as follows: Let CDFB, GJHK (Fig. 2) be pieces of two bodies. They have the form of slabs extending to infinity on all sides. Let the faces CB, JK, which are turned away from one another, be impervious to heat. Let E_1, A_1 denote the radiating power and absorbing power of the body on the left, and E_2, A_2 the radiating power and absorbing power of the body on the right.

Suppose that there is equilibrium of temperature between the two bodies. Then each receives as much heat as it radiates. From the shape of the bodies it is evident that the radiation from each must be normal to their surfaces. It is sufficient, therefore, to consider the unit area of the one surface and the unit area of the other surface opposite it. Consider the energy E_1 originally emitted from 1. A_2E_1 is absorbed by 2, $(1-A_2)E_1$ reflected. Of the reflected energy $(1-A_2)A_1E_1$ is absorbed by 1, $(1-A_2)(1-A_1)E_1$ reflected. Of this $(1-A_2)(1-A_1)A_2E_1$ is absorbed by 2, and so on. It is easy to see that the quantity absorbed by 1 is

$$\begin{aligned}&(1-A_2)A_1E_1+(1-A_2)^2(1-A_1)A_1E_1\\&\qquad+(1-A_2)^3(1-A_1)^2A_1E_1\ldots\\&=(1-A_2)A_1E_1\{1+(1-A_1)(1-A_2)+(1-A_1)^2(1-A_2)^2\ldots\}\\&=\frac{(1-A_2)A_1E_1}{1-(1-A_1)(1-A_2)}.\end{aligned}$$

And the quantity absorbed by 2 is

$$\begin{aligned}&A_2E_1+(1-A_1)(1-A_2)A_2E_1+(1-A_1)^2(1-A_2)^2A_2E_1\ldots\\&=\frac{A_2E_1}{1-(1-A_1)(1-A_2)}.\end{aligned}$$

If we interchange the suffixes we obtain the quantity of the energy E_2 that is absorbed by 1. It is

$$\frac{A_1E_2}{1-(1-A_1)(1-A_2)}.$$

The total quantity of energy absorbed by 1 is

$$\begin{aligned}&\frac{(1-A_2)A_1E_1}{1-(1-A_1)(1-A_2)}+\frac{A_1E_2}{1-(1-A_1)(1-A_2)}\\&=\frac{(1-A_2)A_1E_1+A_1E_2}{A_1+A_2-A_1A_2}.\end{aligned}$$

This must equal E_1. Therefore

$$(1-A_2)A_1E_1+A_1E_2=(A_1+A_2-A_1A_2)E_1.$$

Hence $$A_1E_2=A_2E_1,$$

or $$E_1/A_1=E_2/A_2,$$

which proves the proposition.

The only form of energy considered by the proof is heat. Hence the above quantitative relation holds only for temperature radiation. The body must radiate solely on account

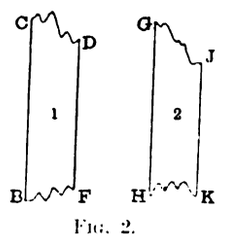

Fig. 2.

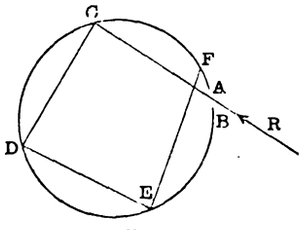

Fig. 3.

of its high temperature, and not in virtue of electromagnetic energy received or of chemical energy liberated. Under this limitation the law is universally accepted as true. Numerous facts point to its truth, and Paschen has verified it quantitatively. How far it holds for luminescence is not known.

A very important result follows at once from the law. A body cannot emit those rays which it totally reflects, or for which it is perfectly transparent. If the surface of the body is a perfect mirror, all the incident light is reflected, none is absorbed and A is equal to zero; again, if the body is transparent, the intensity of the light is not altered by passing through it, and A is again equal to zero. If A is zero, E must also be zero.

In the rigorous proof of his law Kirchhoff introduced the idea of a perfectly black body. A perfectly black body is one for which A = 1 that is, one which absorbs all the rays which fall upon it. Hence, for any given wave-length and temperature no body can radiate more than a black body. None of the surfaces which we are accustomed to regard as black is black in this sense. They all reflect some of the incident light. Black cloth, for example, reflects 1·2 per cent. of the light that falls on it, and black velvet 0·4 per cent. Let the radiating power of the black body be denoted by S. Then $E/A=S$; S gives the ratio of the radiating power to the absorbing power for any body, and is a function of the wave-length and the temperature. Kirchhoff pointed out the importance of determining the function S, and stated that it would undoubtedly be of a simple form, as it was independent of the properties of any particular body. S is sometimes called Kirchhoff's function.

It would be extremely difficult to measure E and A for one particular body for different wave-lengths and thus determine S, for, of course, A would have to be measured at the same temperature as E—that is, while the body is radiating. Paschen commenced a series of researches in 1892 with the purpose of determining S, the method being to measure E for a series of bodies which were more or less black. Then, if these bodies were arranged in order of their "blackness," it would be possible by a species of extrapolation to arrive at the behaviour of the ideal black body. Paschen used a piece of platinum foil folded double, in the fold of which a thermo-element was placed for the purpose of determining its temperature. The foil was heated by a current from a secondary battery, and was coated with the substances the radiation from which was to be examined. The radiation was measured with a bolometer; the spectral apparatus had concave mirrors instead of lenses, and the prism was of fluorite. The substances used were carbon filaments, platinum foil, platinum foil covered with iron oxide, copper oxide and soot. They all behaved pretty much the same with the exception of platinum, which radiated considerably less.

Meanwhile, attempts were being made from the theoretical side to find S as a function of λ and of T, the absolute temperature. In 1896 Wien gave the following expression:—

$$S=\frac{c_1}{\lambda^5}e^{-\frac{c_2}{\lambda T}},$$

which was afterwards derived by Planck in another manner. The proofs are not simple and are not quite beyond question.

The next important step was the experimental realisation of the perfectly black body by Lummer and Pringsheim. A perfectly black body is one that absorbs all the rays that fall on it and reflects none. Consider the accompanying diagram (Fig. 3). It represents a section of a hollow sphere which has a small opening at AB. R is a ray which enters the opening and is reflected in succession at C, D, E and F. The inside surface of the sphere is blackened. Only a small portion of the energy is reflected each time, the greater part being absorbed. The hole AB is of such a size that the chances of the ray finding its way out again are very small. Light falling on AB is practically all absorbed. Consequently, if the sphere be maintained at a uniform temperature, sufficiently high to make its inner surface radiate out heat appreciably, the radiation from AB will be the radiation of the black body for that temperature, or the black radiation for that temperature, as it is called. Also, if any body be heated inside the sphere to the temperature of the latter, the radiation issuing from its surface through the opening will be black radiation.

For low temperatures double-walled vessels were used, the space between the walls being filled with steam, ice, carbon dioxide snow or liquid air, so as to keep the interior at a uniform temperature. The radiation escaped by means of a tube. For high temperatures an electrically-heated body of porcelain was used.

With this apparatus Lummer and Pringsheim first proved Stefan's law for the black body, showing that the radiation was proportional to the fourth power of the absolute temperature. Then in 1899 they published energy curves taken with the same radiators. These energy curves are reproduced in the first (Fig. 4) of the following diagrams.

Thus Kirchhoff's function S was determined as a function of λ for several different values of T. Lummer and Pringsheim's results did not agree so well with Wien's formula as Paschen's results did, and further investigation showed that Lummer and Pringsheim's results were the more accurate. As a result of their work Planck proposed the following formula:

$$S=\frac{c_1}{\lambda^5}\frac{1}{e^{\frac{c_2}{\lambda T}}-1},$$

which he sought to justify on theoretical grounds. It represents the experimental results satisfactorily within the error of observation.

On comparing Planck's formula with Wien's we notice that it is only when $e^{\frac{c_2}{\lambda T}}$ is not large in comparison with 1 that they differ appreciably—that is, only for high temperatures and large values of λ. Wien's formula may thus be regarded as an approximate form of Planck's, and has the advantage of simplicity. From it a number of important results about black body radiation can be deduced.

We have $S=c_1\lambda^{-5}e^{-\frac{c_2}{\lambda T}}$. To find for what values of λ S is a maximum, take the logarithm of S, differentiate it with respect to λ and equate to zero.

$$\text{Log } S=\log c_1-5\log\lambda-\frac{c_2}{\lambda T},$$

$$-\frac{5}{\lambda}+\frac{c_2}{\lambda^2 T}=0,$$

hence

$$\lambda T=\frac{c_2}{5}.$$

Denote the value of λ corresponding to the maximum value of S by λ_m. When T is measured in degrees abs. and λ_m in 10^{-4} cm., $c_2=14{,}500$. Therefore

$$\lambda_m T=2{,}900.$$

As the temperature increases the maximum moves towards the visible spectrum. By substituting λ_m in the expression for S, we find that the maximum value of S increases as the fifth power of the absolute temperature. S always increases with temperature for every value of λ, no matter on which side of the maximum it is.

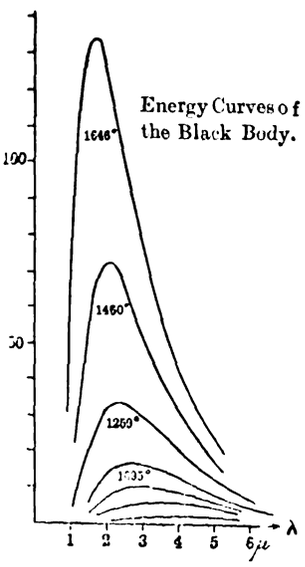

FIG. 4.

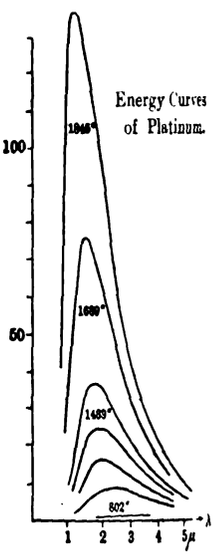

FIG. 5.

To find the total radiation, integrate $\lambda^{-5}e^{\frac{c_2}{\lambda T}}$ from $\lambda=0$ to $\lambda=\infty$. The integration follows easily if λT is put $=1/\theta$, and θ is regarded as the variable. The result is $6T^4/c_2^4$. This is Stefan's law. It holds only for the black body; Stefan thought that it held for all bodies.

The radiant efficiency may be found by integrating S between the limits λ_1 and λ_2 and substituting the values for the ends of the visible spectrum; but there is a more convenient graphical method. When $1/\theta$ is substituted for λT, the integral takes the form $c_1T^4\int\theta^3e^{-c_2\theta}d\theta$. The values of θ corresponding to the ends of the spectrum depend on the value of T. If the curve $\theta^3e^{-c_2\theta}$ be plotted, if ordinates be set up at values of θ corresponding to the ends of the visible spectrum for different temperatures, and if the areas between the ordinates be determined graphically and divided by the area of the whole curve, then we obtain the values of the radiant efficiency for these temperatures. The following results have been obtained in this way:—

Abs. temp.	Radiant efficiency.
1,000	0·0 per cent.
1,500	0·0 „
2,000	1·7 „
3,000	14·6 „
4,000	31·8 „
6,000	49·7 „
8,000	47·7 „
12,000	18·6 „

Digitized by Google

Thus 7,000 deg. abs. gives the most favourable result. Above this the intensity maximum moves into the ultra-violet.

The temperature radiation of bodies that are not black follows more complicated laws. The energy curves vary all the way from shapes not differing widely from that for the black body to curves with two or three sharp maxima. The wave-length of maximum intensity, however, always decreases as the temperature increases, and many substances which radiate selectively at low temperatures become similar to the black body at high temperatures. Of course, no body can radiate more than a black body for any wave-length and temperature.

The metals form an interesting class, and an attempt has been made to represent their energy curves by formulæ of the same form as Wien's, but with a different power of λ in place of the λ^{-5}. At ordinary temperatures they all reflect much better in the infra-red than in the visible spectrum. Hence their absorbing power, and consequently their radiating power, is less in the infra-red. This selective reflection seems to persist at high temperatures, and the energy curves resemble the black body somewhat; but with the ordinates on the infra-red side of the maximum diminished, and consequently the radiant efficiency increased. Lummer and Pringsheim's curves, representing the radiation from glowing platinum at different temperatures, are given by the second (Fig. 5) of the two preceding diagrams. The total radiation from platinum varies as the fifth power of the absolute temperature.

The theory of the black body has been applied in three different ways to the measurement of temperature. Temperature may be read by the hydrogen thermometer up to 600°C., and thence by the nitrogen thermometer to 1,150°C. Beyond this it is customary to use thermo-couples which have been calibrated as far as the gas thermometers go and to extrapolate for values beyond. Thermo-couples are, however, unsuitable for some purposes, and in any case they cannot be used beyond the melting point of platinum. This is where optical pyrometry finds its use.

The first optical method consists in finding the position of λ_m and applying the equation $\lambda_m T = 2{,}900$. The second consists in measuring the total radiation by some instrument such as Féry's thermo-electric telescope and using Stefan's law, or as it is now more often called the Stefan-Boltzmann law. In this instrument an image of the source is formed on a thermo-couple by a concave mirror, and the instrument is calibrated by pointing it at two sources of known temperature. The third method consists in measuring the brightness of the source for one wave-length in the visible spectrum and calibrating the photometer by means of two sources of known temperature.

These methods give relative measurements satisfactorily and enable one to reproduce any temperature with accuracy, which is all that is required for industrial purposes; but they must be used with considerable care if absolute measurements are required. There are many people in possession of optical pyrometers who are, unfortunately, unaware of the limitations of their instrument, and have too profound a faith in its empirical formula.

All three methods hold in the first instance only for the black body. The first method holds also for a "grey" body—that is, one that reflects all colours equally well. In the case of a grey body the ordinates of the energy curve are supposed to be diminished in the same ratio all over and the position of the maximum is unaltered. The first method is, however, not so accurate as the other two, for the position of the maximum cannot be easily determined. The last two methods if applied indiscriminately will not give the true temperature of a body, but its "black" temperature—that is, the temperature of a black body which would have the same total radiation, or which would have the same brightness for the wave-length in question.

To get the true temperature we may proceed in two ways. On the first method, which is due to Lummer and Pringsheim, the scale of the instrument is calibrated by using glowing platinum as well as the black body. We thus have two determinations of the temperature, the second value being that which the body would have if it had the same properties as platinum. As platinum differs widely from the black body as a radiator, there is a presumption that the true temperature of the body will lie between the limits thus obtained. On the second method, the body is placed inside a sphere, the inner surface of which is a good reflector, and the radiation through a hole in the surface examined. The radiation from the body is thus increased until its black temperature equals its true temperature.

Optical pyrometry has been applied to the determination of the temperature of the sun, and values somewhat below 6,000°C. have been obtained and have found their way into the text-books. In a recent Paper (Ann. d. Phys. (4), 25, pp. 905-920, 1908), Dr. A. Goldhammer, however, finds its temperature to be 10,000°C. If the sun is a black radiator at 6,000°C., according to the table given above, this is not far from its most economic temperature. Probably it is not the sun that has adapted its temperature to our eyes, but our eyes which have suited themselves to the sun through long ages of evolution.

(*To be continued.*)

DURATION OF ELECTRICAL CONTACT BETWEEN IMPACTING SPHERES.

In a recent issue of the "Journal of the Franklin Institute" Messrs. A. E. Kennelly and E. F. Northrup contribute an article on this subject. The conclusions reached by the authors are stated by them as follows:—

1. If a metallic sphere impinges either upon another like metallic sphere or upon a hard flat steel surface, the duration of impact is proportional to the diameter of the sphere. (Although this experimental result has not previously been published, so far as the writers are aware, yet this particular fact seems not to be new. In particular, it has been known in the Jefferson Physical Laboratory, at Harvard University, for a number of years.) Consequently, the duration per centimetre of diameter, or "specific duration," depends only on the nature and hardness of the metallic impacting surfaces and on the velocity of impact. By referring then to specific duration, the influence of varying diameter, in what follows, can be eliminated.

2. The harder the metals at their mutually impacting surfaces, the shorter the "specific duration."

3. The "specific duration" is roughly about 20 per cent. greater when a sphere impacts upon an anvil or stationary hard plane surface of a mass large as compared with that of the ball, than when it impacts with a stationary sphere of the same size. This increase in duration is attributable not only to the difference in relative curvature of the impacting surfaces, but also to the fact that in the former case the impinging ball has its velocity approximately reversed before breaking contact; whereas in the latter case the velocity of the impacting ball is merely reduced to zero, the initial velocity being communicated to the impacted ball.

4. Whether the impacting ball strikes another like ball or an anvil, the "specific duration" of impact T_μ/D varies inversely as the $\frac{1}{10}$th root of the vertical drop, h cm., or the $\frac{1}{2}$th root of the impacting velocity, v cm. per second, according to the formula:

$$\frac{T_\mu \text{ microseconds}}{D \text{ cm. diam.}} = \frac{a'}{h^{\frac{1}{10}}} = \frac{a''}{v^{\frac{1}{2}}}$$

where a' and a'' are constants depending on the nature and curvature of the impacting surfaces.

For a copper ball on a steel anvil, $a' = 55$, $a'' = 117$ approximately.
For a steel ball on a steel anvil, $a' = 42$, $a'' = 90$ approximately.
For a steel ball on a steel ball, $a' = 35$, $a'' = 75$ approximately.

WEST HAM CORPORATION ELECTRIC SUPPLY ACCOUNTS.

The West Ham electric supply undertaking has made very satisfactory progress during the past year, and a marked improvement is shown on the previous year's working. This is not altogether indicated by the fact that a deficit of £2,900 has been changed into a surplus of £3,986, since a number of special items have been met in the present accounts. Thus, for the first time consumers' meters have been purchased out of revenue; this has entailed an addition of £1,413 to the expenditure.

There are several features of considerable interest in the report of Mr. H. H. Couzens, engineer and manager of the undertaking, to the Electricity Committee on the year's accounts. The output for private lighting has increased by no less than 15·6 per cent. In view of the extensive use of metal filament lamps, this indicates that the use of electricity for lighting is making rapid strides. As the increase reported last year was only 1 per cent., compared with a considerable decrease in the previous year, it is evident how rapidly the depression brought about by the change-over to high-efficiency lamps has been surmounted.

Power and heating show the large increase of 24·2 per cent., and now are the predominating factor in the total output, accounting for 14,518,555 units out of 22,690,266 units sold for all purposes. The other items included in this total are traction 5,182,257 units, private lighting 2,253,904 units and public lighting 735,550 units.

Whilst the revenue per unit has remained practically constant for lighting—viz., 2·78d., as against 2·79d. a year ago—there is an increase in the revenue per unit received from the power sales. For the 12 months ended March 31st last the average price obtained for power was 0·60d. per unit, compared with 0·58d. in the previous year. Taking the whole of the supply, the average revenue per unit sold was only 0·93d., a similar figure to that recorded last year.

The number of consumers connected to the mains at March 31, 1911, was 2,860, an increase of 306 during the 12 months, a practically similar increase to that recorded a year ago. The motor load has increased by 1,245 H.P., representing 120 new motors connected; and the total number of motors now supplied from the Corporation's mains is 1,119, of 11,558 H.P. in the aggregate.

Considering next the generation of the energy, 28,105,881 units were generated, the maximum demand being 9,404 k.v.a., or 8,123 kw. This represents a load factor of 31·9 per cent., compared with a load factor of 34·38 recorded a year ago. The capacity of the station remains at 11,400 kw. The number of units used on the works was 1,493,090, and 3,922,525 units were lost in distribution, &c.

From the analysis of the accounts which we give below, it will be noticed that on the whole there is a slight reduction in the total cost per unit sold, repairs and maintenance showing some reduction, whilst, owing to the loans taken up during the year, "Corporation stock expenses" have materially increased

There is considerable improvement in the results shown by the Sales Department. Owing to the Local Government Board only granting a period of three years for the repayment of the loans raised for carrying on this Department a heavy burden is placed on its operation. The capital charges on this Department amounted to £1,582 for six months only, so that there will be a considerable increase in this item during the present year. For the period under consideration the capital charges eliminated the profit of over £1,000 in the Sales Department, and result in a deficit of £514 being shown. The above profit was shown by this Department after debiting it with rents, rates, establishment charges, &c.

The item "Special charges," which it will be noted accounts for £3,070 of the total costs, comprises £639 for the replacement of a 1,200 kw. alternator, £240 for the replacement of a stoker, £754 in connection with the old motor hiring scheme, £24 for the extension of offices and £1,413 for the purchase of meters.

The public lighting at the end of the year comprised 363 arc and 182 incandescent lamps. The average price received per unit sold for public lighting was 1·54d.

We give below an analysis of the accounts for the year ended March 31, 1911, the cost per unit sold being tabulated for each item for the year in question and for the previous year.

		Per unit sold. 1910-11.	1909-10.
Generating Costs.			
Coal	£22,087	0·23d.	0·23d.
Oil, waste, water and stores	933	0·01d.	0·01d.
Wages at station	5.180	0·05d.	0·06d.
Repairs and maintenance	3,802	0·04d.	0·05d.
Miscellaneous	610	0·01d.	0·00d.
Total Generating Costs	£32,662	0·34d.	0·35d.
Distribution Costs.			
Repairs and maintenance of mains and services	£1,765	0·02d.	0·02d.
Repairs and maintenance of transformers	992	0·01d.	0·01d.
Repairs and maintenance of meters	1,850	0·02d.	0·02d.
Use of tramway feeders	42	0·00d.	0·00d.
Total Distribution Costs	£4,649	0·05d.	0·05d.
Management Costs.			
Salaries	£2,932	0·03d.	0·04d.
Printing, stationery, &c.	612	0·01d.	0·01d.
Publicity and bulletin expenses	373		
General establishment charges	692	0·01d.	0·01d.
Corporation stock expenses	698	0·01d.	0·00d.
Total Management Costs	£5,307	0·05d.	0·03d.
Attending public and private lamps	£.1937	0·02d.	0·02d.
Rents, rates and taxes	£6,620	0·07d.	0·08d.
Special charges (including insurance and discounts)	£4,170	0·04d.	0·04d.
Sales Department deficit	£514	0·01d.	0·01d.
TOTAL COSTS (*ex.* capital charges)	**£55,859**	**0·591.**	**0·611.**
Capital Charges, &c.			
Interest	£14.619	0·15d.	0·18d.
Sinking fund and repayments	16,411	0·18d.	0·17d.
Contribution to capital account pending borrowing	1	0·00d.	0·03d.
Special works	3,070	0·03d.	0·04d.
Total Capital Charges, &c.	£34.101	0·36d.	0·42d.
TOTAL COSTS (*inc.* capital charges)	**£83,96)**	**0·951.**	**1·03d.**
Revenue.			
Private lighting	£26,581		
Power	37.823		
Traction	21,593		
Heating	252		
Special lighting	353		
Public lighting	6,619		
Interest (hire purchase)	24		
Meter rents, &c.	237		
Miscellaneous	449	—	—
TOTAL REVENUE	**£93,946**	**0·99d.**	**0·99d.**
Balance	£3,936	0·04d. surplus.	0·04d. deficit.

This balance has been allocated as follows: Outstanding debt on accumulators and arc lamp rectifiers £1,757, outstanding debt on transformers and writing down value of 300 kw. set. £2.229.

The capital expenditure during the year was £46,495. mains and services accounting for £12,264, motors on hire £11.931 and Sales Department £9,760 of this total. The total capital expenditure to March 31, 1911, was £503,357, made up as follows:

Land and buildings	£78.385
Machinery and plant	192.164
Tools	525
Mains and service	135.156
Cables, &c.	2.480
Transformers, &c.	42.603
Motors	17.487
Meters and demand indicators	14.705
Electrical instruments	1.224
Lamps and columns	7.355
Office furniture	692
Arc lamps on hire	811
Hire-purchase installation	2.760
Materials, &c.	7.000
Total	£503.357

This represents £44·1 per kilowatt of plant installed in the stations. At the same date the amount of capital repaid or in sinking fund was £135,455, or 26·9 per cent. of the total capital expenditure.

CORRESPONDENCE.

UNITS *V.* RESISTIVITY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The discussion on page 751 in your issue of August 18th by Prof. David Robertson is upon a quite different subject from that of my article of August 11th. My article had the fundamental purpose of clarifying the conceptions of the *quantity*—viz., "resistivity"—and the associated quantities; it was not a discussion of the *names of units*. The latter subject is open to differences of opinion. I purposely avoided the subject, and used only the commonest names of the units, which, though illogically derived, are familiar and of long standing. Questions of scientific nomenclature have always been stumbling blocks, and in the past the efforts of individuals to improve the terminology have frequently added confusion to a complicated situation. It is to be hoped that in the future such questions will be dealt with by scientific congresses, preferably international, and that the efforts of individuals will be directed toward bringing about such congresses.—I am, &c.,

Bureau of Standards, Washington, Aug. 29. J. H. DELLINGER.

CONTINUOUS *versus* INTERMITTENT SERVICE IN PASSENGER TRANSPORTATION.*

BY W. Y. LEWIS.

As regards passenger transportation systems, the situation in all large cities is a very serious one. The travelling habit is increasing directly as the square of the population and in many cities at a greater rate, while notwithstanding the demand for additional facilities, developments are held up owing to the heavy initial and operating cost of subways equipped with electric trains. It is becoming evident, too, that passengers should be handled in streams rather than in crowds. It is obvious if instead of running trains once a minute, and thus damming up the human stream flowing at 3 miles per hour, accommodation at the rate of about three seats per second, moving at a sufficiently low speed to enable passengers to step on and off the cars, were provided, all delay and congestion would be eliminated. There would be no need for a station platform or of trains large and long enough to accommodate the congestion. To meet these requirements the present method consists of trains running at sufficiently short intervals to ensure the passing of at least 10,560 seats per hour. This involves about 35 trains per hour, each of six 50-seat cars. The London Underground can now run trains every 90 seconds at a schedule speed of 15 to 16 miles per hour with stations averaging ½ mile apart. This service intensity corresponds to only about 15 per cent. of the track being occupied by the trains. Thus, the periodic character of the train system is the factor limiting the schedule speed, and consequently the capacity of the system. Intermittency also involves the problem of repeatedly starting and stopping heavy train masses, stresses on the rolling stock and sudden demands on the power house due to acceleration. Acceleration could not be increased without discomfort to passengers, and the average speed from street to street is very low, not exceeding 6 to 7 miles per hour by any of the public services; consequently the loss of time to business men getting about London is still very great. The principal reason why tubes are unable to compete better with surface traffic and render available their superior schedule speeds of 15 to 16 miles per hour is that intermittency is there doubly operative, owing to the use of lifts.

Apparently the only reason why the idea of continuously operating trains has not so far been generally adopted is that the moving platforms, stairways and lifts which have been suggested, operate at a low uniform speed, which perforce has to be sufficiently slow to enable passengers to mount and dismount. The multiple speed platform partially overcame this objection by its series of moving ways, run with a relative speed difference of 3 miles per hour. Still, even with this combination, final speeds above 9 miles per hour cannot easily be attained for the arrangement becomes too cumbersome. It is obvious, therefore, that what is wanted is a continuous system which, whilst providing sufficiently low initial speeds where desired, shall also provide high speeds between stations, so that a high schedule speed, approaching and, if possible, exceeding that of the electric trains, may be obtained. The author then goes on to describe the "A. & L." system, of which he is the joint inventor.

This system is extremely simple. It comprises the provision on a circular route of a series of independent cars, positively controlled and driven by a roller engagement. A shaft extends throughout the route, and is rotated at a constant speed; consequently the speed imparted to the cars is proportional to the pitch of the spiral engaged. To give low speeds at station points the pitch is, therefore, close, and to give high speeds en route the pitch is six or eight times greater, the intermediate pitches to give the necessary acceleration and deceleration being graduated. There is a return of over 80 per cent. of the kinetic energy of the cars during deceleration, instead of a dissipation at the brakes, as in electric traction. Obviously no brake or signal apparatus is required, and many other accessories essential to electric trains are avoided. Compared with a subway equipped with electric traction, the system provides 25 per cent. higher schedule speed when the stations are the same distance apart, 50 per cent. greater capacity when the space occupied is about 30 per cent. less, whilst the operating cost per seat-mile is only one-quarter and the initial cost about one-half.

The shaft is carried in cradle roller bearings of the well-known "anti-friction" type, which, whilst providing for a clear passage, also enable the energy consumption for shaft rotation to be kept so low that the total consumption, including shaft train resistance, train resistance and all losses associated with the efficiency of the elements comprising the system, is only about a quarter, in watt-hours per seat-mile, of the corresponding amount required by electric trains.

The driving motors are inserted at intervals of every ¼ mile. As the size of the shaft is governed by the speeds required, it must be enormously strong for the amount of energy it would be called upon to transmit, and there will be no appreciable twist. The spirals are mounted either on a tubular core or one composed of standard sections, at moderate cost, the construction of the spiral thread being the only element presenting any considerable difficulty.

At first sight the question of wear and tear would appear to be a serious one, but here again the proposition scores heavily. It should be noted that, owing to the substitution by light independent cars of the heavy trains in the present intermittent system, the rolling stock is split up into small units, uniformly distributed over the tracks, and that as there is no necessity to resort to such high crest speeds to get even higher schedule speeds, the result is that the weight of the rolling stock per seat, instead of being from 800 lb. to 1,600 lb., as with electric trains, need not be more than 300 lb. to 400 lb., and even so would furnish infinitely more comfortable riding. Consequently the permanent way calls only for light section rails, which, subjected to such insignificant service, would last indefinitely, compared with those necessitated by electric trains meeting with much more severe treatment. The wear of the spirals would not be great.

As regards safety of operation, owing to the system of driving the cars cannot touch one another, while the whole line can be brought automatically to a standstill in the event of the slightest irregularity. The control of the motors would be centralised, and communication could be established throughout by the usual simple means. The entire route would be brilliantly illuminated.

SUCTION GAS ENGINES AND PRODUCERS.*

A COMPARISON OF TEST PERFORMANCES, WITH RESULTS OBTAINED IN DAILY OPERATION, AND NOTES UPON WORKING COSTS FOR FUEL, OIL, AND LABOUR, &c.

BY W. A. TOOKEY.

Summary.—This Paper comprises a comparison of the test performances of gas plants with the results actually obtained in daily operation. Notes are also given upon the working costs for fuel, oil, labour, &c. The results are given in the form of tables (some of which are abstracted below) and curves. The author shows that gas plant can generally show considerable economy over steam plant, and that it is quite reliable.

It is the object of the present Paper to record in a useful form a series of figures representing the actual performances of suction gas power plants of various types and different powers, not only when tested by some form of brake dynamometer, but also when the output over the period of test can be measured by the generation of electric current or by the raising of water, so taking into account the combined efficiencies of the electric or pumping machinery and that of the gas power plant. Further figures are also presented which have

* Abstract of a Paper read before Section G of the British Association at Portsmouth.

been compiled from the statements of users themselves both in Great Britain and in other parts of the world.

Brake-Horse-power Tests.—It has so long been customary to state that the consumption of coal—anthracite—by suction gas engines and producers is about 1 lb. per brake-horse-power per hour that it is rarely borne in mind that such a statement is made by makers merely for the purpose of stipulating a safe figure in contract guarantees. It will come as a surprise to many, therefore, that in the majority of the tests mentioned the actual consumption of a combined set of engine and producer working with anthracite, irrespective of size, but, naturally, dependent somewhat upon design and the date of manufacture, is between 0·7 and 0·85 lb. per brake-horse-power-hour. It will be observed that the uniformity of coal consumption ranges from about 10 to over 220 B.H.P. Fig. 1 has been plotted from the figures in a Table given in the Paper. Another Table given later in the Paper referring to the performances, under test conditions, of combined suction gas engine and dynamo sets, shows the average figure for fuel consumption to be less than 1·4 lb. per kilowatt-hour, including the efficiencies of the dynamo, and of the method of power transmission employed between the engine and the dynamo.

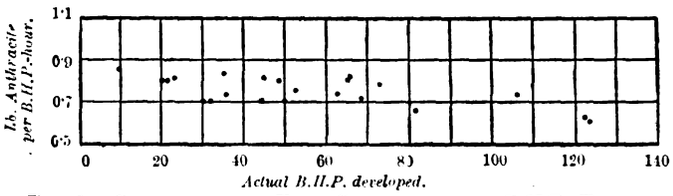

FIG. 1.—CHART SHOWING FUEL CONSUMPTION IN B.H.P. TESTS.

Columns have also been included in the first-mentioned Table to indicate the relative cylinder dimensions and piston speeds of the various engines. Fig. 2 indicates graphically the relation between the actual piston displacement per cycle per minute per brake-horse-power developed, and the coal consumption in lb. per brake-horse-power-hour.

From further figures given in this Table it would appear that the brake-horse-power-hour can still be obtained at half load from less than 1 lb. of anthracite. It is usually stated that the efficiency of gas power plants falls off very considerably when the output is low, but this does not seem to be borne out by facts. In this connection it is interesting to reproduce a chart (Fig. 3), which represents a consumption curve of a Winterthur engine tested by Prof. Aimé Witz in March, 1906. This engine was served with town gas, and the amount of heat admitted to the engine cylinder in the form of gas is plotted against the output of the engine.

Figures in actual Practice.—The factory owner also desires to know what he can expect the average consumption of a gas engine and producer to be when the engine is working throughout the day under

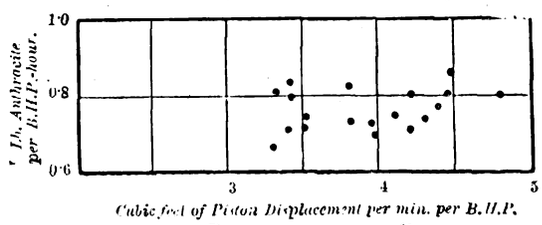

FIG. 2.—CHART SHOWING RELATION BETWEEN CONSUMPTION OF FUEL PER B.H.P.-HOUR AND SPECIFIC PISTON DISPLACEMENT PER B.H.P.-MINUTE.

loads that are ever varying. He wishes to know how far the test figures will be affected by the unavoidable losses due to the continued slow combustion of the fuel during stand-by hours. He also requires information as to probable total fuel consumption when desiring to fix upon the maximum capacity of an engine he is about to purchase.

What are believed by the author to be reliable figures in this connection are given in a second Table. This has been compiled mainly from reports forwarded to the makers of the engines and producers by the users. In order to show more clearly the relation of rated horse-power to hourly consumption of fuel, the accompanying chart has been prepared (Fig. 4). It will be observed that, notwithstanding the great divergence that must exist in the different conditions that apply in individual installations, the results, as plotted, are more uniform than one would expect to be possible. Only in one or two cases do the performances nearly approach the figure that would be reached if the fuel consumed amounted to 1 lb. per rated brake-horse-power-hour, even when, as in all the cases mentioned, stand-by and all other losses are included. It appears that practice, as represented by such figures, well bears out the claims advanced by the makers of suction gas engines and plants. Speaking generally—and none but general assumptions can be made upon such a Table—it would appear that the average consumption of fuel of suction gas plants is at the rate of 0·6 lb. of fuel per rated brake-horse-power per hour, inclusive of all losses.

The more one ponders over the results as set forth in the Table and Fig. 4, the more one wonders that so much power can be procured for so little fuel. Taking the group of engines between 30 and 50 B.H.P., in a score or more of engines, all working with different kinds of fuel, in different districts, in charge of men of different ability, driving machinery at work for a different number of hours per day, and with a different load factor, and with a constantly differing rate of output, involving, apart from differences in the size and styles of producers,

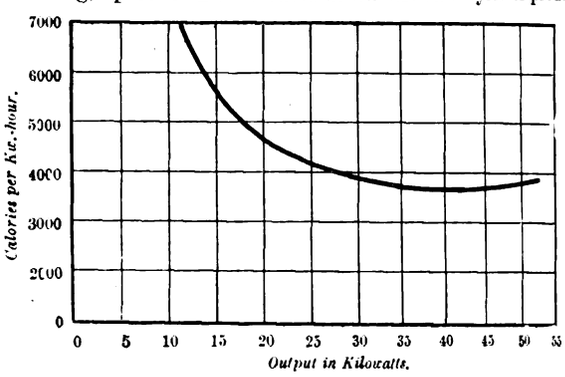

FIG. 3.—CHART SHOWING SLIGHT CHANGE IN COMBINED EFFICIENCY OF GAS ENGINE AND DYNAMO BETWEEN FULL AND HALF LOAD.

different rates of fuel combustion per unit of fire area, a difference of 10 lb. of fuel per hour, or thereabouts, represents the higher and lower limits of fuel consumption. This is a record that stands unrivalled by any other form of prime mover in units of equal size.

It must also be remembered that to obtain the best results from a gas-power plant it is not only the production of good gas that matters, but also the admixture of that gas with a suitable quantity of air to form an explosive mixture within the walls of the engine cylinder. Upon the efficacy of such proportioning of the mixture on the part of the attendant depends the amount of energy obtained per working stroke, and thereby the power and economy of the engine is at once affected. That such low hourly consumptions can be so universally obtained with suction gas plants proves that the attendant is powerless to affect the economy to any appreciable extent, and conversely,

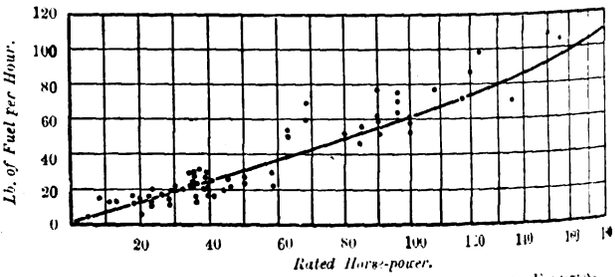

FIG. 4.—ACTUAL HOURLY CONSUMPTION OF FUEL INCLUDING VARIATIONS DUE TO DIFFERENT GRADES OF FUEL, LOAD FLUCTUATIONS, DIFFERENT LOAD FACTORS, LENGTH OF STAND-BY PERIODS, ABILITY OF ATTENDANTS, RATE OF COMBUSTION IN PRODUCER, &c.

that the necessary manipulation is so readily learned that the factory owner can safely rely upon uniformly economical working.

Generation of Electricity.—In the next Table (Table I. herewith) particulars are given of the test performances of a few combined sets

of gas engines, suction gas plants, and dynamos. In spite of the effect produced by the varying efficiency of the dynamos, the different types of engines, and the divergences in producer design and rates of combustion per unit of furnace area, there is little difference to be noted in the relative performance upon the basis of pounds of fuel per kilowatt-hour.

In order to compare the test figures with those obtained per kilowatt-hour in actual practice, with varying load factors and different conditions of working, Table II.* herewith is also presented. From this it is evident that the average consumption, including stand-by losses and other wastage of fuel—the latter being burnt at different rates of combustion and being of different grades of quality—amounts to about 2 lb. of anthracite per kilowatt-hour. In cases where this figure is exceeded it will be observed that the fuel is coke, while in one instance the load is on the engine for only four hours out of the 24 when anthracite is used.

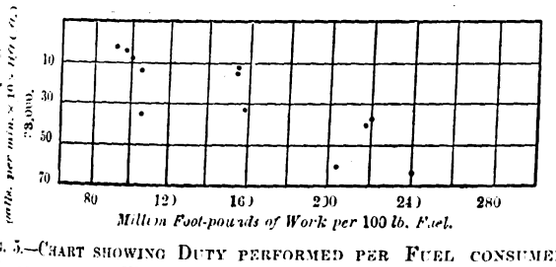

Fig. 5.—Chart showing Duty performed per Fuel consumed in relation to Water Horse-power of Pumping Plants.

Pumping Plants.—The next Table in the Paper records the performances of combined suction gas engines, producers and pumping plants during tests lasting from 5 to 27 hours, with varying types of pumps dealing with quantities of water and heights of lift which indicate that the actual water horse-power exerted ranges from less than 2 to 64. In order that these widely different duties should be brought to a comparable basis the author has computed the number of foot-lbs. of work performed by each set per 100 lb. of fuel consumed. The results obtained differ greatly as shown in Fig. 5, but in view of the undoubtedly uniform results given by the engines and producers as evidenced by the previous Tables, it can be stated with confidence that the divergences are due more to the varying efficiencies of the pumping machinery than to the gas-power plant.

A further table shows the performances of the combined pumping plants under ordinary conditions of working. Three instances in which it is possible to make a comparison with the test figures show that, taking into account fuel wastage from all causes, the hourly consumption of coal in every-day work is increased from 18 to 28 per cent., as compared with the "test" result.

General Reliability.—Much has been stated at various times with regard to the lack of strength or "sensitiveness" of some portions of the mechanism of a gas engine which makes it unreliable. But, after all, the question of reliability is largely dependent upon the ability of the attendant. If the driver fails to detect the development of a fault, and omits the "stitch in time," it is indisputable that a gas-power plant is more liable to sudden interruptions than steam. This does not infer that it is necessary for the attendant to stand by the engine during the whole period of working. Occasional inspection only is called for; but this should be given carefully, thoughtfully, and systematically. Experience soon shows the parts most likely to give trouble, and once these are kept under watchful care, long-continued operation is secured.

A number of users' reports as to reliability are set out in the Paper. These include a run of 1,465 consecutive hours in the case of a 96 H.P. Hornsby Stockport engine, a similar engine of 50 H.P. running 144 hours per week, without stop, and other instances of long runs.

The statement made by, or on behalf of, the Workington Bridge & Boiler Co. well summarises the matter in question: "As regards reliability, there is practically nothing in it between the two; possibly the steam plant has the advantage, if anything, as regards actual stoppage." This is the opinion of the firm in question after making a change from steam power, comprising a compound, horizontal, enclosed type of engine, with forced lubrication, supplied with steam at 80 lb. pressure from a Lancashire boiler. This almost equal reliability has been obtained simultaneously with a reduction in working costs from 1·195d. to 0·452d. per unit, including fuel, labour, oil, water, repairs, &c.

Elasticity of Output.—Recent improvements in design have done much to increase the elasticity of the gas engine. At the present time most British makers are offering engines of both "hit-and-miss" and "throttle-governing" methods of speed regulation; but there can be little doubt that if no question of price came into consideration, and if no choice were to be submitted, users generally would accept the throttle-governed engine and admit its great advantages. It is not the fractional saving of coal of one method of governing over the other that matters, even if that were positively in favour of either; but it is the greater smoothness of running, the graduated force derived from consecutive explosions instead of a greater or lesser number of explosions of full intensity, that makes for so distinct an improvement, while the diminution of working stresses in the more important working parts gives consequent longer life.

But there is another improvement that has synchronised with the development of the throttle-governed engine and which has been somewhat overlooked, or, at all events, not properly appreciated, and that is the increased rotative speed of the later types of gas engines. The higher speed of revolution that is now common practice, coupled with the improved method of throttle governing, undoubtedly brings the gas engine into a more favourable position to withstand the criticism of lack of overload capacity that has so frequently been levelled against it.

Consumption of Lubricating Oil.—Another considerable improvement that has recently been effected is in connection with methods of lubrication. The common practice of older types of gas engines consisted of fitting some form of mechanical lubricator supplying a practically unalterable quantity of oil to one end of a tube communicating with the walls of the cylinder. This tube was intended to lead the oil to both the piston and the gudgeon pin bearing, but in fact dispersed as much oil over the paintwork of the engine as found its way to the intended destination. For the bearings, lubrication by worsted wicks was deemed sufficiently good practice.

In the most modern engines, the lubrication of the cylinder and the gudgeon pin are separately provided for. Forced lubrication is fitted to the cylinder and piston, the quantity of oil pumped per stroke being adjustable to meet varying grades of oil and varying temperatures which affect viscosity. The main bearings are provided with oiling rings. As may be imagined, the consumption of lubricating oil has now been brought down to extremely low figures, while, after

* This Table, as well as Table I., has here been curtailed.—Ed. *E.*

Digitized by Google

filtration, most of the oil can be used again upon the line shafting and general machinery of the factory.

For convenience of keeping works costs, the consumption of lubricating oil is usually referred to in comparison with the actual or estimated output of the engine. This, however, does not seem to the author to be a correct method of record keeping. So long as the engine is running, the oil consumption is in direct relation to the engine speed and not to the output of power. In the latest types of gas engines there appears to be a fair degree of uniformity in oil consumption, to some extent independent of size. Some of the measured quantities supplied to engines of various powers over an extended period of working are given in Table III; in some cases the total oil used has been remarkably small, on account of the re-use of filtered oil.

Consumption of Water.—In all the records that the author has been able to collect there are very few reliable figures which indicate the consumption of water for washing the gas, for generating water vapour in the producer, and for cooling the engine cylinder. The reason for this is that the water service is taken from the mains supplying the other portions of the factory.

From M. Mathot's tests, actual figures under test conditions are noted for a few engines in Table IV. The quantity of water used greatly depends upon the men in charge.

Combined Costs of Fuel, Oil and Labour.—Table V. shows a few of the actual working costs per hour of engines of various sizes, given in a large Table in the Paper.

From this Table it can be claimed, without fear of contradiction, that suction gas engines and producers enable users of power to obtain the means of driving their factories at extremely low cost, and in these days of keen commercial competition it suggests that they may well consider whether it would not be economical to instal gas power in preference to existing methods of power generation, which, although probably adequate as regards power, and reliable in everyday work, are interior to the gas power installation in respect to the whole of the working expenses attached to them.

Repairs and Renewals.—Low cost of operation, however, would not in itself be a sufficient basis for comparison. Consideration must also be given to the amount of repairs necessary and the expense attached to renewals. Information collected and presented in a Table in the Paper shows that for periods varying from one to seven years the expense for upkeep of the gas power plant is practically negligible. The author's experience in this matter extends over many years of working of individual installations, and with but one or two exceptions he can confirm the statements made by the users of the engines. Naturally, much depends upon the attendant, and if compensation for wear and tear be neglected, and if the "stitch in time" is not given, the engine will continue to operate until "something happens." Then either a big bill has to be faced for an expensive overhaul, or a smaller amount is spent in making as good a job as possible for the money.

The chief items of expense occur in the renewal of piston rings, refacing and, perhaps, renewal of exhaust valve, reboring or renewal of cylinder liner. The bearings require occasional refitting, but rarely need relining. As far as the piston rings are concerned, the usual rate of renewal is at the rate of one a year. The exhaust valve may need to be replaced about every four or five years, while the life of a liner and piston can be taken as an average at about seven years. Of course these periods vary according to the actual number of hours worked during the periods referred to, and according to the attention given to minor matters, such as rebushing of levers, replacement of worn pins and spindles, which, if neglected, may cause excessive deterioration of other working parts.

As far as the producer is concerned, the firebricks lining the generator require to be renewed about every two years, for which the material costs little; but the time occupied in dismantling and re-erecting runs into about three days. Generators made with sheet-steel casing will usually require patching around the portion exposed to the action of the heated moist gases within the ashpit after about five years of work, and perhaps renewal of this portion about every seven years. Cast-iron is preferable for this portion of the apparatus, but is only used for the smaller powers on account of first cost. Fire-bars will be wanted about every two years, or at longer periods, unless the fire is worked at a high temperature, arising from an insufficiency of steam, which causes burning out.

The cost of these renewals and repairs, which from their record would appear to be somewhat high, are not actually more than would be required to cover the cost of similar work in connection with steam plants, including the cost of cleaning, scaling and preparing boilers for inspection, repairs to feed pumps, and other auxiliary apparatus. Indeed, as will be seen from the information given in the Table, one firm with an engine and producer of 120 H.P. capacity estimate that they save £7 per annum over the charges incurred for the upkeep of the steam plant previously in use.

Capital Outlay.—For the purpose of computing the average cost of installing gas engines and suction gas producers, the author has decided not to take into account any approximate figure for the cost of space occupied, or for any special buildings erected for their special housing, owing to the very few instances that occur in practice when it becomes necessary to do otherwise than fit them up in some corner of a factory already in existence. The prices indicated in Fig. 6 include the cost of the engine, producer, pulley, water circulating tanks, piping (to what gas engines makers call "standard arrangement"—that is, when the component parts are disposed within about 20 ft. from one central point), foundation and builders' work, and labour in erection.

As a basis, the ruling prices listed by two different makers have been plotted, additions being made for the builders' work and for labour, according to the author's experience of what may be considered average "fixings." These prices are probably on the high side, but will be quite sufficiently correct for rough estimating purposes.

Table V.—*Combined Costs for Fuel, Oil and Attendance.*

Maker and H.P.	User.	Remarks.	Fuel. Pence per hour.	Labour. Pence per hour.	Oil & Stores. Pence per hour.	Total Pence per hour.
Campbell, 96	Martin & Co., Hull	Coke breeze	5·67	6·9	0·41	13·

Digitized by Google

It will be seen that from 150 to 50 B.H.P. the total cost is at the rate of about £7·5 to £8 per brake-horse-power. From 40 B.H.P. downwards the rate per brake-horse-power increases, ranging from about £9 to £11·5 in the smallest sizes.

Comparison with Diesel Engines.—There is no doubt that the Diesel engine, as made by firms possessing wide experience in their design and operation, permits a nearer approach to the ideal efficiency with regard to the conversion of heat units available into work than any other motor yet produced. Repeated tests have shown that as much as 42 per cent of the total heat value of the fuel is represented by the work performed upon the piston of the engine as recorded by the indicator, whereas the equivalent of a consumption of 0·7 lb. of anthracite per brake horse-power-hour with a combination of gas engine and suction gas producer would represent a thermal efficiency on the indicated-horse-power basis of but 31 per cent.

The consumption of liquid fuel per brake-horse-power with a Diesel engine is usually at the rate of 0·45 lb. per hour. The price of the oil fluctuates according to the ruling market prices, and for the present purposes can be fixed at 50s. per ton. At this rate, the cost per brake-horse-power-hour is about 0·12d

Upon the basis of 0·7 lb. of anthracite per brake-horse-power-hour at 30s. per ton, the cost of fuel for the suction gas plant is 0·1125d. It will be seen, therefore, that as far as fuel cost alone is concerned, there is not very much to choose between the Diesel and suction gas engines, and the decision to instal the one or the other must rest upon other considerations. One very serious consideration, to the disadvantage of the Diesel engine, is the matter of capital outlay, involving, as this does, not only increased annual standing charges for interest on the sums expended beyond the relative cost of a suction gas installation of equal power, but also the allowance for depreciation must be increased in proportion.

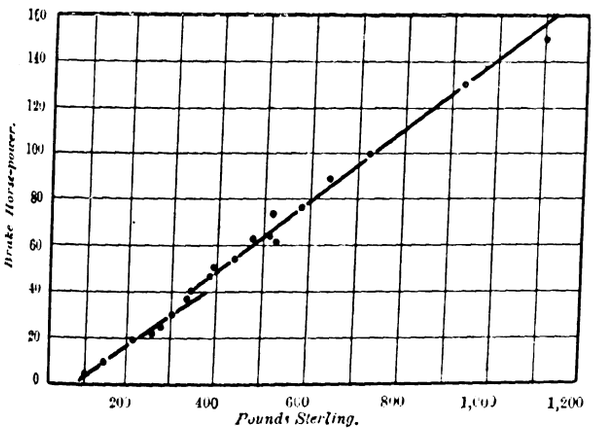

FIG. 6.—CAPITAL OUTLAY, INCLUDING ENGINE PRODUCER, PIPES AND ACCESSORIES, FOUNDATIONS AND ERECTION.

There is no warrant for a general assumption of superiority, as far as total costs of running are concerned, in favour of either one or the other motor; but in few factories is a skilled engineer not required by the type of industrial machinery, so it will not be seriously challenged that in that factory there is no room for a Diesel engine.

Comparison with Semi-stationary Steam Engines.—Semi-stationary steam engines combined with a high-pressure boiler with superheater, jet condenser, with two-stage or compound expansion, have come to the front during recent years. From test results, it has been found that under full loads the consumption of fuel per brake-horse-power-hour has been brought to the low figure of approximately 1 lb. of coal, and this being so, the steam engine has been able to show to much better advantage than ever before in competition with the suction gas engine.

From the circumstances inseparable from steam generation, however, this remarkably low consumption cannot be maintained in actual operation with the same continuity as, from the Tables presented in this Paper, has been proved to be existent with the gas power plant. This is due to the gradual formation of scale within the boiler, the sooting up of the superheating tubes by the flue gases, and the general lessening of efficiency, only to be restored by frequent periodical cleaning and overhaul.

In the latest designs of semi-stationary engines special attention has been given to accessibility of the boiler tubes and to the superheater, to enable the necessary cleaning to be carried out with thoroughness and despatch; but from the point of view of the gas engine builder, this only accentuates the inherent defects of the steam plant. With a gas engine there is no excessive temperature or high pressure in any part of the apparatus other than within the engine cylinder, and then only for but a fraction of a second. This in itself is no slight recommendation.

A further advantage in favour of the suction gas engine and producer is that with the latter the attendant can be engaged in other work throughout the factory, and need give only occasional inspection when fuel charging at long intervals. With the steam plant, a man has to be constantly in attendance to keep the fire going, while it is well known that the manner in which the stoking is carried out frequently affects the fuel consumption by as much as 15 to 20 per cent.

When it is remembered that for the best results to be maintained it is advisable to adopt some system of water softening and purification, and that the cost of the whole equipment is thereby increased far beyond the cost of the gas power plant, it will be recognised that the advantages of the latter are still further emphasised. Especially is this so when the engine is required to deal with a load much above or below the rated power of the plant, or for unsteady and widely varying outputs. In the one case the economical limits of condensing steam engines are sharply defined, while the liability of sudden fluctuation of load must involve some waste of fuel due to the blowing off of excess steam from the safety valves, due to the natural anxiety of the stoker to have his plant ready for any emergency.

THE ELECTRICAL CONDUCTIVITY OF LIGHT ALUMINIUM ALLOYS.*

BY PROF. ERNEST WILSON.

The physical properties of certain light aluminium alloys have formed the subject of several communications,† and, as stated therein, a specimen of each alloy has been placed on the roof of King's College, London, in order to investigate the influence of exposure upon electrical conductivity. Another light alloy of aluminium known as "Duralumin" has recently been added, and the result of exposure will be duly investigated, but for the moment only certain of its electrical properties are dealt with in this Paper. All the specimens are in the form of wire 0·126 in. (3·2 mm.) diameter. The results are set forth in the following table.

Copper.—It has been pointed out that the deterioration of the copper series increases with the percentage of copper. Specimen No. 15 contains 2·61 per cent. copper, and has so far corroded that it broke when being bent into a loop for attachment to the bridge. For this reason the percentage increase found in 1908 has been inserted in the table. Specimen No. 14 has also corroded, but not to the extent of No. 15. Alloying commercial aluminium with copper *alone* is not to be recommended, except in very small quantity.

Copper-Manganese.—It is interesting to note that specimen No. 23, containing 1·78 per cent. manganese, has not seriously deteriorated during 10 years' exposure. It has a fairly high breaking load of 35,000 lb.

Copper-Nickel.—Specimen No. 22 is remarkable in that it has a small temperature coefficient and a breaking load of 45,900 lb. Its resistance has increased to the extent of 18·7 per cent. in 10 years.

Duralumin.—This alloy is stated‡ to contain about ½ per cent. magnesium, 3½ to 5½ per cent. copper, ½ to $\frac{8}{10}$ per cent. manganese. It has recently attracted attention in that a breaking load of about 90,000 lb. can be obtained if desired, according to treatment. The specimen No. 26 used in these tests is the B quality, and has a breaking load of about 67,000 lb. (30 tons), and from 12 to 15 per cent. elongation. As received, specimen 26 has a specific resistance at 15°C. of $5{\cdot}35 \times 10^{-6}$ ohms. It has a length of about 76 ft., and was wound on a wooden drum 12 in. diameter before placing in an oil bath for temperature coefficient experiments. During the first heat to 110°C. the figures given in the table (specimen No. 26) were obtained, and it is interesting to note that the temperature coefficient is almost exactly the same as the copper-nickel alloy No. 22. The effect of the first heat to 110°C. has been to lower the specific resistance by about 1·3 per cent., but subsequent heating to the same maximum has had practically no further effect. This alloy becomes brittle after heating in a Bunsen flame and allowing to cool in air. It is stated§ to have a melting point of about 650°C. It will be

* Paper read before Section G of the British Association.

interesting to see the effect which exposure will have upon the electrical resistance of this alloy, for which purpose it is suspended with the other specimens on the roof of King's College, London.

It is unfortunate that if tested for breaking load the samples would be rendered useless for further exposure tests, as they are none too long at present. The author, however, feels sure that alloying commercial aluminium with certain materials, for example manganese, in proper proportions will have a beneficial effect upon durability as well upon tensile strength.

Rail-less Trolley Traction.—An interesting report upon the working of the rail-less trolley system of traction at Bradford has been prepared for the Tramways Committee by the tramways manager, Mr. C. J. Spencer.

A rail-less trolley service was commenced in June along Sticker-lane between Laisterdyke and Dudley-hill, linking up two of the routes from the city. Mr. Spencer, who had been requested to consider what districts might be profitably served by an installation of the system, states that from an engineering and operating point of view the rail-less trolley system has been an unqualified success. No serious difficulties of any sort have cropped up on the Laisterdyke–Dudley-hill experimental section, such as might have reasonably been expected in connection with a new installation. From the traffic revenue point of view the returns are not quite up to anticipations. They had no experience of the traffic value of a cross-town route in Bradford, and Mr. Spencer is surprised to find that instead of a 10 to 20 minutes' service being required for the district a 15 to 30 minutes' service seemed to be ample to meet normal requirements. The route was very short and hardly served a sufficiently wide area to test fairly the traffic possibilities of the district. In all probability the traffic revenue will improve very considerably when the route is extended, with suitable overlapping stages. Mr. Spencer recommends several extensions of the system within the city, making up a total route mileage recommended of 9 miles 13 yds., and costing about £13,500 for street equipment. Assuming an average service of 15 minutes, 12 cars would be required, including spares, at an estimated cost of £9,000, and depôt accommodation would cost £4,000. The total amount of capital required, therefore, would be £26,500, and the annual charges would be £2,247.

The Tramways Committee have adopted the report and have added to the proposed routes one of a distance of about 2 miles. In connection with this Mr. Spencer reported that it would undoubtedly be a suitable route if arrangements could be made with certain authorities outside Bradford. The Committee have also decided to confer with the Bingley local authority in regard to tramway facilities in the Bingley district.

LEGAL INTELLIGENCE.

Electricity Generating Station Regulations.

At Jarrow, on 7th inst., Palmer's Shipbuilding & Iron Co. were summoned for having committed a breach of the Home Office Regulations for the Use of Electricity in Factories and Workshops.

Mr. W. B. Lauder, H.M. Inspector, said regulation 21 provided that where necessary, to prevent danger by metal becoming charged, earthing or some other method of protection should be adopted. On July 7 a man named Byers, a driller, while using a radial drilling machine on a steel plate, received a fatal electric shock, and two other men received shocks in trying to get him away from the tool. The whole plate had become charged through a puncture in the cable, but if it had been earthed that would not have been possible. No steps had been taken to meet the regulations, although the machine had been erected two months.

The offence was admitted, and Alfred Baker, foreman electrician, said that the drill and other machines which were not earthed had been erected, while he was away, by his assistant, but earthing was such an elementary precaution he had not thought it necessary to see that it had been done. He should have done so.

A fine of £10 was imposed.

Coal Mines Regulations.

At the Manchester County Police Court on Thursday last week, a haulage lad named Fred Beresford, employed by the Clifton & Kearsley Colliery Co. at their Newtown No. 2 pit, at Clifton, was charged with having committed a breach of the special rules under the Coal Mines Regulation Act.

For the prosecution it was stated that the offence with which defendant was charged was that he had interfered with the electric cable which ran along one side of the main haulage road. On the evening of Aug. 11 a hammer was found on the top of a girder, and it was alleged that defendant had acted in such a way as to make both the girder and the hammer "alive with electricity." Anyone who happened to pass under the girder would be liable to get an electric shock from current at 220 volts. Last year there were four deaths in this country by miners receiving shocks from current at 200 to 250 volts. Another serious matter was that at the time of the discovery the lives of between 400 and 500 men were endangered, as if any sparks had flown and come into contact with the dust in the pit an explosion might have taken place.

Defendant, when asked whether he had anything to say, said he "did not do it." The magistrates fined him 10s., and costs.

COMMERCIAL AND INDUSTRIAL SECTION.

MUNICIPAL, FOREIGN & GENERAL NOTES.

BRITISH NOTES.

Armadale (N.B.).—Mr. Geo. Balfour has intimated that he will apply for a provisional electric lighting order.

Bampton (Devon).—The Council have sealed an agreement with Dr. J. W. Purves, for the public electric light for £49 a year for se ven years. Current will be available in three months and the scheme will be completed in nine months.

Brighton.—The Council decided on Thursday last that, before adopting the report of the borough electrical engineer, Mr. John Christie, recommending reductions of charges for electrical energy, abolition of meter rents, &c. (referred to in our last issue), a report be obtained from the Borough Accountant as to the financial effect of the proposals.

Burnham.—The Council have resolved to apply for a provisional electric lighting order.

Cotton Mill Driving.—The firm who recently took over the Norfolk-street Rink, Darwen, have put in about 70 looms and the machinery is being driven by electric motors.

Dover.—The borough electrical engineer (Mr. L. W. Woodman) has been authorised to prepare a report upon the question of providing adequate coal storage facilities.

Electric Stoking Plant for Gas Works.—On Monday Perth Council adopted a recommendation to adopt electric stoking plant at the local gas works at an estimate cost of £3,900.

Exhibitions.—The 10th International Motor Exhibition will be held at Olympia, London, from Nov. 3 to 11. Particulars from the Society of Motor Manufacturers & Traders, Maxwell House, Arundel-street, London, W.C.

An International Smoke Abatement Exhibition will be held at the Royal Agricultural Hall, London, from March 23 to April 4, 1912. Particulars from Mr. F. W. Bridges, Balfour House, Finsbury-pavement, London, E.C.

The Baku branch of the Imperial Russian Technical Society is organising an international engineering exhibition at Baku (Russia) in April next.

Among the chief exhibits will be electric motors, internal combustion engines, air compressors and other equipment for oilfield development. Reduced railway charges from Batoum to Baku have been arranged for the exhibits, and at the close these will be returned freight free to Batoum, whence there are regular sailings to England. No duty is payable on the exhibition goods entering Russia. The exhibition will remain open for six weeks. Dr. P. Dvorkovitz, 1, Broad-street-place, London, E.C., is the official honorary representative of the exhibition in England.

Farnham.—The Council have considered a report from the Public Works Committee on a proposal to substitute suction gas plant for steam power at the sewage pumping station.

The Farnham Gas and Electricity Co. recently offered to supply motors and electric current for sewage pumping and it has been decided that, provided the company reduce their terms from £240 to £210 per annum (the estimated annual cost of a suction gas plant) and provided an agreement with the company for a term of 10 years can be satisfactorily arranged, the Council will adopt electric pumping.

Forthcoming Books.—Messrs. S. Rentell & Co. will shortly publish a new book by Mr. W. Perren Maycock, entitled "Small Switches, &c., and their Circuits."

"The Electrician" Company will have ready next week Mr. H. Broughton's great book, "Electric Cranes and Hoists: their Design, Construction and Application." Price 25s. nett; postage to U.K., 1s. 8d. abroad.

The book is the first volume of a complete manual on lifting and hauling machinery, and it deals in a comprehensive manner with the design, construction and application of electrically-driven cranes.

Glasgow.—The Tramways Committee have further considered the tramway extension schemes which at the last meeting of the Council were held over for a week. A statement was submitted by the manager (Mr. J. Dalrymple) showing the probable cost of the various schemes, which had been recommended. It was decided to revive the scheme for the extension of the line from Baillieston to Coatdyke.

Hawes (Yorks).—A meeting of the parish electors has approved a proposed agreement with Mr. E. Chapman for the electric lighting of the streets for 20s. per annum.

Herne Bay.—The Board of Trade have deferred the question of the revocation of the provisional order for 12 months. A public meeting of ratepayers is to be held to discuss the steps to be taken to carry out the terms of the order.

Holmfirth (Yorks.).—A ratepayers' meeting has approved of the Council's electricity supply scheme.

Kilsyth (N.B.).—The Council have been notified by a London company of its intention to apply for a provisional electric lighting order.

Leigh (Lancs.).—Sanction has been received to a loan of £5,300 for additional generating plant.

Llanelly.—The demand for electrical energy for power and lighting is increasing very rapidly and additional plant is being put down by the company. The Pemberton tinplate works are being electrically driven, and a scheme is being prepared to use electricity throughout the Copper Works.

National Electrical Manufacturers' Association (Inc.).—The proposals for the reorganisation of the work of this association have now been successfully carried through and will shortly be put into effect.

They include alteration of title of the association (which will in future be known as "The British Electrical and Allied Manufacturers' Association (Inc.)"), appointment of a new secretary (vice Mr. F. O. B. Hawes, resigned) and of a larger working staff, leasing of offices in a central position and certain necessary amendments of the constitution, including the revision of qualifications for members, associate members and associates, &c. The new secretary of the association is Mr. D. N. Dunlop, sales manager of the British Westinghouse Company's supply department, manager of the publishing department and superintendent of the printing bureau, at Trafford Park, Manchester. Mr. Dunlop was unanimously elected secretary at the meeting of the Council on 7th inst., and has been empowered as from that date to begin the reorganisation of the association. Mr. Dunlop's appointment dates from Jan. 1, 1912.

Nelson.—The agreement with Colne & Trawden Light Railway Co. for through running between Nelson Centre and Laneshawbridge and Trawden has been continued for six months further, and two new cars are to be purchased for the Colne and Trawden light railway.

Penmaenmawr.—The whole of the promenade, about a mile in length, is now illuminated electrically.

Presentation.—On his marriage, Mr. W. F. Rathbone has been presented by the Norwich staff of the National Telephone Co. with fish knives, and a case of fish carvers and serviette rings, and by the Tunbridge Wells staff with a silver tea kettle and sugar tongs.

Sheffield.—Various extensions of mains, estimated to cost about £500, are to be carried out and tenders are to be invited for a new water-tube boiler.

Small Power and Model Engineering Exhibition.—The third exhibition of small power engineering appliances, models and scientific apparatus, organised by the proprietors of "The Model Engineer," will be held at the R.H. Hall, Vincent-square, Westminster, London, S.W., from Oct. 13 to 21.

A feature will be a completely equipped model engineering workshop in which demonstrations of metal working processes and small engine building will be given. Particulars from 26-29, Poppin's-court, Fleet-street, London, E.C.

Swansea.—At the end of August there were 2,137 consumers of the electricity supply department (an increase of 63), and the equivalent of 28,750 32-watt lamps was connected.

Torquay.—The Council have received sanction to a loan of £5,250 for additional plant at the electricity works, the period for repayment being 17 years.

Wimbledon.—The Council has received sanctions to a loan of £2,993 for h.t. mains, £3,600 for l.t. mains and house services, and £110 for meters. The L.G. Board have deferred their decision as to £750 for sub-stations and transformers.

Marriage.—The marriage took place on Sept. 7 of Mr. Douglas Gray, manager of Keighley Corporation tramways, and Miss E. M. Rhodes, eldest daughter of the Mayor of the borough, Ald. S. Rhodes.

Digitized by Google

COLONIAL AND FOREIGN NOTES.

Angola (West Africa).—A Consular report states that the Lobito, Benguella & Catumbella Electric Light & Power Co., formed to supply the three townships and surrounding districts with electric light and power, is a British company, and the consulting engineers are Sir Douglas Fox & Partners. The contractors for the generating plant are Messrs. Johnson & Phillips.

The falls on the Catumbella river, 3 miles from Catumbella Town, are being utilised. A dam is being constructed which will give a minimum of 4,000 B.H.P. at the driest period of the year. The present power-house will have a capacity of 1,800 B.H.P., of which 900 B.H.P. is now being installed. The work is well advanced. All the materials for the work have been brought from the United Kingdom and landed at Lobito, from which place they are distributed over the Benguella Railway. Overhead transmission lines (carrying three-phase current at 20,000 volts) are taken to Catumbella (3 miles) and from there to Lobito (8 miles) and Benguella (14 miles). The lines consist of copper wires attached to porcelain insulators on steel poles. The town of Catumbella (which embraces Lobito) undertakes to use 300 lights (from 16 to 32 c.p. each) for street lighting in Catumbella and 100 in Lobito. The town of Benguella will use 1,000 lights for street lighting. The demand for private lighting in Catumbella and Benguella is considerable, as the business houses are busy and prosperous, and the only form of illuminant at present is oil, except for a few acetylene gas plants. There is also likely to be a considerable demand for power for irrigation. At Lobito the railway company will probably require a considerable amount of energy both for light and power. For the present, provision is being made for: Catumbella, 150 B.H.P.; Lobito, 150 B.H.P.; Benguella, 300 B.H.P.

Work was begun in connection with the Lobito electric lighting concession in May, 1910. In May, 1911, about one-half of the river had been dammed and sluice gates erected. It is probable that all will be running order by the end of this year. Poles have been erected at Benguella, Catumbella and Lobito.

Amongst the works projected for St. Thomé for the current year is the supply of electricity for lighting and power.

Australasia.—The "Australian Mining Standard" says the electric lighting plant at Euroa (Victoria) was recently started. This is all British, and consists of an 81 H.P. suction gas engine, a 44 kw. generator and a storage battery. The price for current is 8d. per unit for lighting and 4d. for power.

The Australian General Electric Co. have entered into a contract for the erection of a 1,000 kw. plant for supply of energy at the Victorian State coal mine (Victoria).

The Supply Bill recently passed by New South Wales Parliament provides for expenditure of £1,300,000 on railways and tramways, £15,000 towards cost of Moree–Mungindi railway, and £40,000 for tramway construction.

Redfern (N.S.W.) Council have agreed to sell their electric generating plant to Sydney Council for £20,000.

Drummoyne (N.S.W.) Council have accepted the offer of Sydney Council for supply of electrical energy for lighting and power.

The Agent-General for Tasmania (Sir John McCall) recently stated at an interview that in order to provide cheap power for the iron mines of the northern area of Tasmania, the waters of the Great Lake are to be tapped. The first proposal is to put down turbines of 20,000 H.P. Nearly half this power will be utilised at North-West Bay, near Hobart, where it is proposed to erect metallurgical works to deal with refractory ores from the north coast of Tasmania, and probably also from Broken Hill (N.S.W.)

Austria-Hungary.—The Allgemeine Oesterreichisch-Ungarische Gasgesellschaft has purchased the Mödling gas works and has offered to establish electricity works, and to construct an electric tramway either direct to Vienna or to Wiener Neudorf to join the Vienna-Baden line. The communal authorities have appointed a committee to consider the matter.

Railless trolley cars are to be run from Müglitz through the northern Moravian towns of Meedl, Neustadt, Aussee and Mürau.

A syndicate has been formed to carry out the project for the equipment of hydro-electric works on the Danube, near Pressburg, with a capacity of 70,000 H.P. Dr. M. Hoor-Tempis, of Buda Pest, is one of the promoters.

Japan.—A report by the acting commercial attaché of the British Embassy, Tokio, shows that Japanese imports of machinery in 1910 were of the value of £1,606,700, decrease £465,800 compared with 1909.

The machinery included dynamos and motors £123,300 (compared with £184,400 in 1909), other electrical machinery £100,400 (against £121,800), lifting machines £33,300 (£189,900), steam boilers £49,500 (£93,200), steam engines £61,800 (£72,000), gas, oil and hot air engines £53,200 (£39,100), pumping machines £52,900 (£45,100), steam turbines £15,200 (£23,700), mining machinery £10,400 (£7,800), and telephones £30,300 (£12,200). Of the £1,606,700 worth of machinery the following were the contributions of the countries mentioned: United Kingdom £954,500 (£1,409,000), U.S.A. £370,500 (£382,500), Germany £237,800 (£252,800), France £9,800 (£12,000), other countries £34,100 (£16,100).

The gradual improvement in trade in 1910 had not been in existence long enough by the end of the year to affect the amount of the annual import, but to judge from the amount of capital invested in new and the extension of old industrial concerns during the year the prospects of the machinery business for the coming year are comparatively rosy. Other factors conducing towards the same end were the organisation of a large hydro-electric power scheme and preparations for establishing two or three more similar undertakings; also the passing by the Diet of a bill for subsidising light railways. The alteration of the tariff which took place in July caused orders to be placed for machinery to be delivered before the new tariff came into force. An interesting feature has been the increase in the use of gas engines. Factories, small municipal electric light undertakings and similar enterprises have recently begun to instal suction gas plants for the generation of power where water-power is unavailable, as gas is found cheaper than steam or oil. At the end of the year the Imperial Government Railway Board made a contract with a British firm for the erection of gas-driven electricity works. Speaking generally, gas engines imported are chiefly of British manufacture.

The import of telephones represents chiefly desk and office telephones. The telephone service is a Government undertaking, and the authorities have not been able to keep pace with the large number of applications for installations which are continually being received. At the end of the year there were 128,000 telephones in operation throughout the country and 66,000 applicants waiting to be supplied. The Government obtains telephones from two factories in Tokio, one of which is a Japanese and the other a joint American-Japanese concern. Telephone cables are imported, but doubtless an attempt will soon be made to manufacture them in Japan. It is feared that the alteration of the tariff from an ad val. to a specific basis as regards most kinds of machinery will exercise rather an unfavourable influence.

It is stated that the Government have authorised Tokio municipality to take over the electric tramways of the city as from Aug. 1. It is proposed to abolish 13 or 14 miles of the existing lines and to construct five new lines, three of which were especially ordered by the Government to be completed by July 31, 1916. An endeavour is to be made to finish the whole of the lines by the end of 1914. The municipal authorities propose to build about 500 new cars. It is stated that the change has caused a great deal of discussion in municipal and political circles as it is thought that it will be but the beginning of the wholesale municipalisation of tramway, electric lighting and gas supply undertakings. It is stated that electric lighting will be the first to be transferred to the city, for the Tokio electric tramways have their own electric lighting department, which the city will now have to maintain. Strong public feeling was aroused against the change, for there seemed a general fear that the practical result would be a raising of the fares.

Russia.—Archangel municipal authorities are raising a loan of 1,000,000 roubles (about £105,000) for the construction of an electric tramway, the erection of electricity works, &c.

Spain.—A recent U.S.A. Cnsular report on the trade of this country says:—

There is a brisk demand at Valencia for dynamos, motors and all kinds of electrical supplies, as well as for pumps of 2 H.P. to 12 H.P. The available electrical energy in the district has been recently increased by an additional 6,000 H.P., making in all about 13,000 H.P., in consequence of which the demand for every class of machinery workable by electricity is rapidly advancing. Pumps, motors and dynamos are made in the country, but some are still imported. The trade is worked through agencies at Barcelona or Madrid, as there are no wholesale merchants or importing jobbers at Valencia. The Thomson-Houston and the Siemens-Halske Co.s have established branch houses at Valencia. There are three classes of local agents, but in no case does the agent bear any of the initial expense, and it is owing to this difficulty, together with the fact that provincial dealers are used to buying from travelling salesmen in Barcelona or Madrid and not to importing direct, that probably 90 per cent. of all foreign exporters doing business in Spain have either appointed general agents or have opened branch houses at one of the two cities mentioned.

Imports at Bilbao in 1910 included 42 tons of electrical machinery and fittings from the United Kingdom out of a total of 284 tons, an increase on former years, but, consisting principally of purchases by a British mining company.

A Consular report from San Sebastian states that an electric line is in course of construction from San Sebastian to Hendaye (the frontier town) and is expected to be ready for traffic by June, 1912. A tramway is being constructed from the important town of Tolosa to the frontier, taking in all the towns and villages on the way. Very little of the material employed in these enterprises is of British origin. Belgians and Germans appear to monopolise this trade, cheapness being the chief point.

Sweden.—A Consular report from the Gothenburg District states that in 1910 there was an important increase in the amount of water-power made available.

21 hydro-electric installations have been completed, 20 are projected, installations, varying from 300 H.P. to the Stora Kopparbergs Bergslags Aktiebolag's station at Bullerforsen with 24,000 H.P. and the Svenska Kraftaktiebolaget's last two stations of 10,000 H.P. The Trollhätta installation (40,000 H.P.), is the largest of them all. In addition, installations, totalling 7,650 H.P., were rebuilt during the year. Four building seven private water-power installations with a total of 63,000 and the installation by the State at Porjus (50,000 H.P.), also commenced during the year, will raise the total horse-power at the stations being to 115,000.

A report from Halenstad says the great power plant on the Lagan River was opened by the King on Sept. 17. An extension has already been decided upon.

Digitized by Google

At Helsingborg one of the older harbour basins has been extended and partially rebuilt, and electric cranes for discharging cargoes of coal and minerals will be erected.

Plans have been adopted for the erection of electrical works at Ystad, which are expected to be completed in the course of next year.

Wireless Telegraph Notes.—A report from Boston, U.S.A., is to the effect that a wireless telegraph station, to be established at Charlestown Navy Yard, will be the most important and most powerful official station of the U.S. Government on the Atlantic Coast, and will enable the shores of the entire North Atlantic Ocean to be in intercommunication, from the north coast of Ireland to the Caribbean Sea; 3,200 miles is the distance given. Coast shipping from above Newfoundland to south of the Gulf of Mexico will be in touch with Boston.

Travellers via Cape Horn will learn with interest that a powerful installation of wireless telegraphy is to be erected near Port Stanley in the Falkland Islands, the point usually made by vessels which meet with difficulties on this route. The station will be capable of communicating as far as Monte Video.

The following hails from Los Angeles, in California: Mr. Peard is editor of the "Herald," and he was recently holiday-making at Avalon. A wireless message was sent to him which was intercepted by some amateur wireless operators (who, by the way, abound in the United States). These amateurs got the message and forthwith took it to Mr. Earl, who is editor of the rival "Tribune." Mr. Earl published the message without asking questions. It appears that the message originated with General Otis, who had been conducting a newspaper war with the "Tribune." The General had Mr. Earl arrested for having "stolen" his message. A novel legal point immediately arose as to whether messages sent through the air, where they can be read by anyone and everyone possessing a receiver, could be called private or be copyrighted. As the message was sent by a private person the State is not a party to this interesting legal duel. In the meantime Mr. Earl is out on bail, and newspaper folk are watching the sequel with considerable interest.

ELECTRICITY SUPPLY AND TRAMWAY ACCOUNTS.

Aberdeen.—The accounts of the electricity department for the year ended July 31 last show that the total capital expenditure is £373,375, of which £73,587 has been repaid.

Revenue was £21,201, gross profit £26,352. After meeting capital charges, £1,984 has been carried to reserve. Units generated were 7,094,900 (against 6,416,276 in previous year), supplied to private consumers 3,597,727 (3,141,749), for public lighting 281,325 (291,435), for Corporation tramways 1,903,084 (1,856,089), for Suburban tramways 140,000(146,792). Fuel costs were 0·30d. per unit sold (against 0·31d. works costs were 0·48d. (0·50d.), total costs (exclusive of capital charges) 0·79d. (0·81d.)

Bath.—The accounts of the electricity department for the year ended March last, presented to the City Council last week, show revenue £20,435, and working and general expenses £10,718. 7s. The gross profit was £9,708. 12s. 2d., and the net deficit £616.

Bridlington.—The accounts of the electricity supply undertaking for the year ended March last show capital expenditure £41,547 (increase £2,928), of which £6,199 has been repaid.

Revenue was £5,998 (against £5,598 in previous year), and working and general costs were £2,344 (compared with £2,710), and, after meeting capital charges and contributing £220 out of revenue for meters, £33 to machinery insurance account, &c., the net profit was £10,007 (against £437). Units generated were 444,443, supplied to public lamps 174,509 and to private consumers 210,966. The maximum supply demanded was 922 kw. Coal cost was 0·488d. per unit sold (against 0·573d.), and total working cost 1·455d. (against 1·831d.).

Middlesbrough.—The accounts of the electric lighting department for the year ended March last show capital expenditure £116,658 (increase £2,758), of which £31,227 has been redeemed.

Revenue was £18,852, total costs £9,668, net profit £2,079 (after providing for interest and redemption, interest and sinking fund £7,105). Works costs were 0·890d. per unit sold (against 0·889d. in previous year), total costs were 1·147d. (1.219d.) and interest and redemption of capital required 0·843d. (0·942d.). The total number of units sold was 2,021,886.

Sheffield.—The annual report and accounts of the tramways department for the year ended March was submitted to the Council on Wednesday.

Total annual revenue was £323,098 (increase £20,606), including £316,738. 17s. 4d. passenger traffic revenue. Working expenses were £186,024. 10s. 9d., and gross profit was £133,735. 7s. 10d. (increase £16,098. 3s. 2d.). The amount transferred for relief of rates (£26,541. 8s. 3d.) is the highest on record. 84,500,331 passengers were carried and 7,618,383 car-miles run.

The Tramways Committee have considered the alternative routes suggested for the proposed Upperthorpe tramway, and after receiving the report of the general manager and surveyor, the committee re-affirmed their previous decision recommending the construction of a tramway from Infirmary-road on the Hillsborough section along Albert-terrace-road and Oxford-street into Crookes Valley-road, there joining the Walkley route opposite Harcourt-road.

At the meeting of the Corporation on Wednesday, Ald. Bennett submitted the annual statement of accounts of the electric lighting department, and expressed satisfaction at the fact that the year's working showed an improvement on the previous year of £5,452. The increased use of current for power represented an increase of 56 per cent. He could not hope that the department would be able for some years to come to make any contribution to the rates, because, owing to the increased demand, they would have to incur additional capital expenditure.

Councillor Neal suggested that the electric light and tramway power stations should be connected by cable to provide against possible difficulties owing to strikes.

In replying to the discussion, Ald. Bennett said he was unable to hold out any hope of a further reduction in price for shopkeepers.

TRADE NOTES AND NOTICES.

TENDERS INVITED.

Tenders are invited up to Nov. 21 for supply of one automatic or semi-automatic switchboard and equipment to the Postmaster-General's Department in Western Australia. Tender forms and specifications may be obtained at the Commonwealth Offices, 72, Victoria-street, London, S.W. See an advertisement.

Tenders are invited up to Oct. 18 for the supply of 20 coin-in-the-slot attachments to the Postmaster-General's Department in Western Australia. Specifications, forms of tender, &c., may be obtained at the Commonwealth Office, 72, Victoria-street, London, S.W. See advertisement.

The Postmaster-General's Department in South Australia require tenders up to Oct. 25 for supply of cable and paper sleeves. Tender forms and specifications may be obtained from the Commonwealth Office, 72, Victoria-street, London, S.W. See also an advertisement.

Tenders are invited by the City of Melbourne for the supply of 8,000 yds. three inch fibre conduit, suitable for laying underground in concrete, and to be used for containing lead-covered cables. Specification, tender form and conditions of tender from the Agents for the City Council, Messrs. Mellwraith, McEacharn & Co. Ppty. (Ltd.), Billiter-square-buildings, London, E.C., to whom tenders by noon of Tuesday, Oct. 3. See also an advertisement.

London County Council require tenders by 11 a.m. Oct. 24 for supply of hand-power overhead crane, h.t. and l.t. cables and switchgear, &c., rotary converters and static transformers, for sub-stations. Specifications, &c., from the Clerk.

Manchester Markets Committee require tenders by Sept. 25 for supply and erection of electrical and mechanical plant and wiring at the cold air stores, Elm-street, Manchester. Specification from the Superintendent.

Manchester Electricity Committee require tenders by noon, Oct. 4, for supply and erection of a 4,000—4,500 kw. low-pressure exhaust type turbo-alternator. Specification from the Secretary, Town Hall, Manchester.

Keighley Council require tenders by Sept. 25 for supply and erection of coal handling plant and water storage reservoir and pumps for the electricity department. Specification, &c., from the Borough Electrical Engineer.

Durban (Natal) Corporation require tenders by Sept. 25 for supply of 6 miles of steel girder tram rails (95 lb. per yd.), with fish plates, bolts and nuts, tie bars and copper bonds. Specifications from Messrs. Webster, Steel & Co., London, E.C.

Dover Guardians have accepted the tender of John Wright & Sons for supply of an indoor telephone at £16. 12s. 9d. The National Telephone Co. also tendered at £16. 1s. 5d.

Hastings Guardians require tenders by Oct. 18 for the electric lighting of the workhouse premises, Ore, Hastings. Spesification from Mr. S. Bumstead, 11, Wellington-sq., Hastings.

Bray (Ireland) Council require tenders by Sept. 19 for supply of 2,500 yds. 7/18 S.W.G. concentric paper-insulated and lead-covered cable.

Winnipeg (Canada) municipality require tenders by Sept. 25 for fire apparatus, including 30 fire-alarm boxes. Specifications from the Chief of the Fire Department, Central Fire Station, Winnipeg.

Tenders are invited up to Sept. 26 for supply of telephone material and 30 miles of telephone cable, up to Oct. 2 for supply of 10,000 porcelain insulators to Postmaster-General's department in Tasmania, and up to Oct. 3 for the supply of 42 miles o

Digitized by Google

telephone cable to the Postmaster-General's department in VICTORIA. Tender forms and specifications at the Commonwealth Office, 72, Victoria-street, London, S.W.

The Metropolitan Water and Sewerage Board, Albert-street, BRISBANE, Queensland, want tenders by noon Jan. 30 next for supply and erection of one, two or three complete units, each consisting of power generating plant and pump or pumps to lift not less than 6,000,000 gallons per day. Particulars from the Secretary, and forms from the Agent-General for Queensland.

DUNEDIN (N.Z.) Corporation require tenders by Nov. 1 for supply of (1) 500 B.H.P. vertical type gas engine or Diesel oil engine, suitable for rope driving an a.c. motor and d.c. generator; and (2) direct-coupled vertical type gas engine or Diesel oil engine and d.c. generator (800 kw. at 550 volts). Specification at 73, Basinghall-street, London, E.C.

TULCEA (Roumania) municipality require tenders by Nov. 19 for electric lighting of the town.

Tenders are required for the erection and equipment of an electric power station at the port of VARNA (Bulgaria). Tenders to the Section des Finances of the Railways and Ports Department, Sofia, by 3 p.m. Sept. 30.

Tenders are invited by the Municipal Council of PELOTAS (Brazil) for a 40 years' concession for the supply of electricity for power and lighting and the establishment and working of electric tramways. Tenders to Senhor Luiz M. da S. Pennafiel, Intendencia Municipal, Pelotas, up to 1 p.m. Nov. 14. A deposit (about £300) is required with each tender, to be increased by the successful tenderer to 25,000 milreis (about £1,670). Further particulars (in Portuguese) can be seen by British contractors at 73, Basinghall-street, London, E.C.

The Municipal Council of BUDAPEST, Hungary, require tenders for the manufacture and supply of plant for a steam-driven electrical generating station, including two groups of three-phase turbo-generators (5,000 kw. each), 10,000 volts 50 cycles, boiler equipment for mechanical output of 5,000 kw. with reserve, pipeline, central switching and accessory equipments, travelling crane for engine room and coal-conveying plant. Specifications, &c., can be obtained at the Presidial Section of the Council, 9: IV., Városház-utca 16, II. 1, Budapest. Tenders by 11 a.m. Sept. 30.

Tenders will be received at the Town Hall, SYZRAN, Russia, on Oct. 14, for the construction of an electric tramway and the supply of electrical energy for lighting.

Tenders will be received on Sept. 25 at the Central Military Telegraphy Stores, Boul. de Latour-Maubourg, PARIS, for supply of 1,500 kg. of 6-10 mm. bi-metallic wire.

Tenders will be received at the Italian State Railway offices ROME, on Sept. 26 for supply of five cranes (one electric) and on Oct. 3 for three electric cranes.

Tenders will be received at the Town Hall, GRAZALEMA, Spain, on Sept. 29 for the town electric lighting for 20 years.

Tenders will be received at the Austrian State Railway Offices, VILLACH, on Sept. 19 for supply of a cylindrical compressor with a.c. motor, &c.

TENDERS RECEIVED AND ACCEPTED.

The Great Eastern Railway Co. have placed an order with Royce Limited for 11 electric capstans, 10 electric jib cranes and two electrical hoists and spares for the company's wharf and goods yard at Blackwall.

Sheffield Council have accepted the tender of the British Thomson-Houston Co. for supply of 50 R.G.E. traction motors at £100 each for the Tramways Department.

Melbourne Council have accepted the tender of the local electric supply company for supplying current for cluster lamps, at 30s. each per annum, and for tantalum lamps at 15s. each.

Worksop Council have accepted the tender of Nalder Bros. & Thompson for switchboard instruments and that of the Rhodes Motors (Ltd.) for alterations to booster.

Salford Council have accepted the following tenders:—

Crompton & Co., d.c. generator for Ladywell Sanatorium, £139; Johnson & Phillips, wiring health and water offices, £124, with £12 for contingencies; Aiton & Co., c.i. discharge pipes for circulating water, £20.

Dudley Council has accepted the tender of the Worthington Pump Co. (at £390) for additions to the air and circulating pumps of the condenser plant at the generating station.

The tender of Falk, Stadelmann & Co. has been accepted by the Metropolitan Asylums Board for supply of metal filament lamps to Grove Hospital.

Gateshead & District Tramways Co. have placed an order with Chamberlain & Hookham for equipment of their cars with meters.

Wolverhampton Electricity Committee have accepted the following tenders:—

Chloride Electrical Storage Co., 230 cell storage battery (£9,260) and also for the annual maintenance; Phœnix Dynamo Mfg. Co., two motor-driven boosters, £1,538; Electric Construction Co., battery switchgear, £1,058; Bruce Peebles & Co., 400 kw. rotary converters, £1,060.

Stockport Council have accepted the following tenders:—

McClure & Whitfield, spare motor, £38. 10s.; Dussek Bitumen Co., bitumen, £5. 10s. per ton; Evershed & Vignolles, recording meter, £8. 16s. 10d.; British Insulated & Helsby Cables, trolley wire, 32 in. bonds, £8. 18s. 6d. per 100, 8 in. ditto, £5 per 100.

Nelson Council have placed an order with Davidson & Co., Belfast, for a 40 in. induced draught fan for the electricity station.

Wolverhampton Council have accepted the tender of J. Cave & Sons for additions to the generating station at £6,000.

Commonwealth P.O. Contracts.—The Australian Postmaster-General's Department has accepted the following tenders:—

Victoria.—India Rubber, Gutta Percha & Telegraph Works Co., earth plates, brass nuts and screws, £144; J. Bartram & Son, magnets, microphones, &c., £428; Cameron & Sutherland, desiccating plant, £135; Williams & Co., 15,000 spindles, £312. 10s.; Western Electric Co., 350 duplex translators, £188; Lacy-Hulbert & Co., petrol-driven winch, £164. 10s.; Burrough's Adding Machine Co., one electric duplex adding machine and one normal duplex adding machine, £340.

The Victorian Railways Department have accepted the tender of the Australian General Electric Co. for supply of 150 telegraph relays at £4. 4s. 7d. each.

South Australia Works and Buildings Department have accepted the tender of Unbehaun & Johnstone for an electric lighting installation in a public library at £314.

N.S.W.—Burrough's Adding Machine Co., four electric adding machines, £620.

Queensland.—C. Monteath & Sons, 150 tons c.i. pipes, £9. 13s. 10d.; B.I. & Helsby Cables, 5,000 copper pockets, £55. 19s. 10d., 40 gross connecting screws 1½d. each, and 6,000 zincs 6¾d. each; Dalgety & Co., 6 tons magnesia, £5. 2s. 6d.; J. Bartram & Son, 5 tons sal-ammoniac, £35 per ton; India Rubber, Gutta Percha & Telegraph Works Co., 2,000 zincs, 1s. 1½d. each; Lawrence & Hanson, 20,000 copper binders 56s. 6d. per 1,000, 15,000 copper binders 46s. 6d. per 1,000, 20,000 copper binders 17s. 6d. per 1,000, 2,500 copper sleeves 47s. per 1,000, 20,000 copper tapes for 70 lb. wire 14s. per 1,000, 15 tons phosphor-bronze wire £75. 10s. per ton, 2,000 leads 4d. each, 1,000 zincs £8. 5s., 2,000 zincs £155. 16s., and 2,000 zincs £468. 15s.; T. Zwicker & Co., 4,000 copper sleeves £5. 12s. 6d. per 1,000, 2,000 ditto £4. 12s. 6d. per 1,000, and 10,000 sleeves £5 per 1,000; Western Electric Co., 10,000 sleeves, £8. 7s. 6d. per 1,000; British General Electric Co., 20,000 copper tapes at 27s. 11d. per 1,000, supply of 15,000 copper tapes for 200 lb. wire at 27s. 11d. per 1,000, 1,500 pots 2s. 2d. each and 8,000 pots 1s. 4½d. each; Webster & Co., 3 tons g. steel wire, £20. 17s. 6d. per ton; W. T. Henley's Telegraph Works Co., 5,280 yds. cable, £186 per mile; Siemens Bros. & Co., 12 local spring inkwriter registers, £16. 11s. each.

BUSINESS NOTICES.

Messrs. W. T. Glover & Co. have removed their Glasgow offices and stores to 158, Hope-street. The telephone number is changed to 3856 Douglas, the telegraphic address remaining "Conductor Glasgow."

Messrs. Paterson & Service, 38, Bath-street, Glasgow, have been appointed sole agents for Scotland for the Walsall Electrical Co.

The Imperial Lighting Co. ask us to announce that the fire which occurred recently at their Pocock-street premises was practically confined to the packing department. Business will be carried on as usual.

Sale by Auction.—Messrs. Fuller, Horsey, Sons & Cassell will include in their sale by auction at H.M. Dockyard, Portsmouth, on Tuesday, Oct. 10, and following days at 11 a.m., 10 tons white metal, 50 tons scrap brass and mixed metal, 1,200 tons mild scrap steel, 700 tons wrought and c.i. scrap, 190 tons old steel tubes, 117 tons old wire rope, 26 tons zinc bottoms, ashes and scrap zinc, 2 tons lead ashes, 50 tons old electric cable, electric fans and electrical stores, tools, &c. May be viewed three days' prior to and on mornings of sale, and catalogues, 6d. each, had at the Dockyard, or of the Auctioneers, 11, Billiter-square, London, E.C., and 100, King-street, Manchester. See also an advertisement.

Plant for Sale.—Mr. Alex. Mein, Station-street, Stratford, London, E., advertises for sale a Crompton three-phase alternator, switchboard, &c.

Patent Development.—The owners of patents No. 23,501/99, relating to "Improvements in vacuum tube lighting," and No. 12,582/02, relating to "An improved system of electric lighting," desire to negotiate with electrical engineers with the view of granting licences. Applications to Messrs. Lloyd Wise & Co., patent agents, 46, Lincoln's Inn Fields, W.C.

Agency.—A German firm of accumulator manufacturers advertises

Digitized by Google

for a London firm with a connection among motor-car makers, &c., to take over the sole agency of their portable accumulators.

"The Journal."—Part 209 of the "Journal" of the Institution of Electrical Engineers is now ready, price 5s. For particulars of contents see advertisement.

Imports.—The following are official values of electrical machinery material and apparatus imported into this country (*a*) during August, 1911, and (*b*) during the current year from Jan. 1 to Aug. 31, with the increases or decreases compared with the corresponding periods of 1910:—

Electrical machinery (*a*) £87,756 (increase £27,402), (*b*) £715,117 (increase £331,619); telegraph and telephone cables (*a*) £17,337 (increase £5,178), (*b*) £244,491 (increase £152,635); telegraph and telephone apparatus (*a*) £16,553 (decrease £1,604), (*b*) £113,991 (decrease £3,772); other electrical wires and cables, rubber insulated (*a*) £5,405 (decrease £12,278), (*b*) £57,006 (decrease £81,072); with other insulations, (*a*) £3,114 (increase £1,136), (*b*) £24,307 (increase £4,969); carbons (*a*) £8,798 (decrease £3,414), (*b*) £81,377 (decrease £9,051); glow lamps (*a*) £19,940 (decrease £33,795), (*b*) £188,528 (decrease £185,934); arc lamps and electric searchlights (*a*) £201 (decrease £55), (*b*) £1,073 (decrease £1,208); parts of arc lamps and searchlights (other than carbons), (*a*) £6,180 (decrease £2,028), (*b*) £68,307 (increase £19,907); primary and secondary batteries (*a*) £2,770 (decrease £925), (*b*) £28,046 (increase £412). Total of electrical goods and apparatus, other than machinery and telegraph and telephone wire, (*a*) £92,150 (decrease £43,378), (*b*) £887,215 (decrease £89,404).

Exports.—The exports of electrical machinery, material, &c. (*a*) during August, 1911, and (*b*) during the current year from Jan. 1 to Aug. 31, and the increases and decreases compared with the corresponding periods of 1910, are as follows:—

Electrical machinery, (*a*) £160,701 (increase £25,619), (*b*) £1,162,754 (increase £135,997); telegraph and telephone cables (*a*) £84,023 (decrease £353,700), (*b*) £496,672 (decrease £971,144); telegraph and telephone apparatus (*a*) £16,813 (decrease £15,617), (*b*) £168,209 (decrease £35,645); other electrical wires and cables, rubber insulated (*a*) £27,595 (decrease £32,691), (*b*) £261,004 (decrease £27,605); with other insulations (*a*) £28,547 (decrease £11,506), (*b*) £496,672 (decrease £971,144); carbons, (*a*) £991 (decrease £855), (*b*) £11,069 (decrease £638); glow lamps (*a*) £14,172 (increase £4,531), (*b*) £104,589 (increase £22,583); arc lamps and searchlights, (*a*) £1,402 (decrease £1,754), (*b*) £12,319 (decrease £1,859); parts of arc lamps and searchlights (other than carbons), (*a*) £1,238 (decrease £471), (*b*) £10,817 (increase £1,076); primary and secondary batteries (*a*) £19,914 (increase £9,287), (*b*) £10,024 (increase £19,575). Total of electrical goods and apparatus, other than machinery and telegraph and telephone wire, (*a*) £239,287 (decrease £400,960), (*b*) £1,781,520 decrease £821,516).

BANKRUPTCIES, LIQUIDATIONS, &c.

A dividend is to be paid to creditors of Geo. Valentine Barker, electrical engineer, Gledhow Wood-grove, Roundhay, and John-street, Albert-street, Harrogate. Claims to Mr. D. S. Mackay, Red House, Duncombe-place, York, by Sept. 23.

The trustee (Mr. E. S. Grey, Bankruptcy Buildings, London, W.C.) in the bankruptcy of Morris Zains, lately electrical engineer, &c., of 98 and 105, Wardour-street, London, W., has been released.

The trustee (Mr. F. T. Holcomb, King-street, Newcastle, Staffs.) in the bankruptcy of John Wm. Barnett, electrical engineer, 25, Waterloo-street, Burslem, has been released.

Silicaware Limited is being wound up voluntarily, and Mr. P. W. Straus, 7, Great Winchester-street, London, E.C., has been appointed liquidator.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

*Note.—The undermentioned Applications (except those marked †) are not open to public inspection until after acceptance of Complete Specifications. Those marked * are open for inspection 12 months after the date attached to them, if they have not been published previously in the ordinary course. Names within parentheses are those of communicators of inventions. When complete Specification accompanies application, an asterisk is affixed.*

17,502 Furneaux & Rock. Electric switches.
17,516 Mehne. Apparatus operated by clockwork for turning on and off lighting arrangements at given times. (Addition to 14,052/09.)*
17,518 Griffiths & Comissiong. Electrical timing devices for races and the like.
17,519 Fairbrother. (Vesta Accumulator Co., U.S.) Adjustable electric lamps.*
17,530 Gwozdz. Telephones. (Addition to 11,234/11. Convention date, 21/4/11, Germany.)*

SPECIFICATIONS PUBLISHED.

1910 Specifications.

9,775 Olvis. Switching means for dynamos for charging accumulators.
12,931 Friedmann. Joint boxes for electric wiring. (1/12/10.) (Convention date not granted.)
13,035 Gabreau. Electric lighting for vehicles.
17,126 Hawley (Ltd.), Saunders & Jones. Electromagnetic separator, drum or pulley.
17,322 Kessels. Printing telegraph instruments.
17,349 Electric & Ordnance Accessories Co., Garner & Mubller. Controllers for use in connection with electro-motors.
17,650 Helfenstein. Electric furnace. (27/7/09.)
18,012 Hallstream. Electric contact mechanism for the automatic stopping of machines.
18,190 Adams Mfg. Co. (Cutler Hammer Mfg. Co.). Controllers for electric motors.
18,191 Adams Mfg. Co. (Cutler Hammer Mfg. Co.) Electric motor controllers.
18,195 Brown, Boveri & Co. (Akt.-Ges. Brown, Boveri & Cie. Dynamo-electric machinery.
18,241 Wardle. Lamps or lanterns for incandescent electric lamps.
18,300 Ges. fur Chemische Industrie in Basel. Apparatus for the electrolysis of fused alkali chlorides. (22/12/09.)
18,306 Adams Mfg. Co. (Cutler Hammer Mfg. Co.) Means for controlling dynamo-electric machines.

18,656 RENTON. Flexible cord attachment for electric lamp-holders.
18,680 RIDEAL. Utilisation of the silent electric discharge.
18,631 LANCHESTER. Propulsion of vehicles by combination of prime mover and electrical storage.
19,608 SMITH. Incandescent vapour lamps.
19,851 REYROLLE & REYROLLE & Co. Electrical cut-outs.
19,972 RITCHIE. Telewriter apparatus.
20,257 LEITNER. Automatic electric switches.
20,685 SUTTON & SUTTON. Controlling the connection and disconnection of a plurality of electrical circuits to or from another such circuit.
20,696 GIRARDELLI & HOLZMAN. Electric time alarm device.
20,995 ELECTRIC & ORDNANCE ACCESSORIES CO. & MUELLER. Combined electric switch and fuse distribution boxes for use with electric cranes.
21,080 GRAY. Electric portable lamps for use in mines and other places.
22,355 ETCHELLS. Push-button electric switches for controlling electric lifts and the like. (9/3/11.)
23,066 B.T.-H. Co. & MARTIN. Electric meters.
23,153 BULLERS (LTD.) & DAGNALL. Method of supporting electric cables or wires and means therefor.
23,669 NEUHOLD. Automatic telephone systems. (27/10/09.)
23,807 FLETCHER & DALE. Sparking plugs for internal combustion engines.
23,902 HIRST & ARCHER. Electric heating irons (1/11/10.)
24,485 FIELD & FERRANTI. Electrical resistances.
26,856 HABERMANN. Morse transmitter.
27,144 KLUPATHY & BERGER. Submarine audible telegraphy and signalling. (30/7/10.)
27,804 SPEAKMAN. Electrical insulators for use in mines. (29/11/09.)
30,390 POPP. Electric furnaces. (6/5/10.)

1911 SPECIFICATIONS.

1,028 SMITH & PLATT. Ignition plugs for internal combustion engines.
1,909 ADAM. Electric tightening devices for cable conveyors. (26/1/10.)
3,151 TRIBELHORN. Driving mechanism for electrically-propelled vehicles.
3,272 BULLERS (LTD.) & TWISS. Electric insulators.
3,648 WEINTRAUB. Electrolytic meters. (14/2/10.)
4,457 ELECTRIC & ORDNANCE ACCESSORIES Co. & COLLINS. Time limit or retarding devices for use with electric circuit-breakers.
4,602 TIMAR & PRESSER. Process for the closing of the seams of tubes by means of electrical resistance welding. (2/5/10.)
4,724 OCHS. Device for continually rolling about a number of articles by means of endless bands for electrical or mechanical treatment.
4,806 PARKES. Construction of electromagnets for indicators, relays and similar apparatus.
5,167 B.T.-H. Co. (G.E. Co.) Insulating material.
6,182 WASSERZIER. Electric ignition device for gas burners.
6,526 DOWSING. Apparatus for the application of radiant heat or light to the human body.
6,861 WALLACE & GRAHAM. Electrical switch or controlling device
6,862 WALLACE & GRAHAM. Electrical time switch.
7,045 FRIED. KRUPP AKT.-GES. Continuous electric current generators with separate excitation. (16/5/10.)
7,501 SIEMENS SCHUCKERTWERKE GES. Arc lamps. (26/3/10.)
7,569 FRISBY. Electric current detectors or apparatus for detecting the presence and direction of electric current.
7,736 SCHATTNER. Rheostats.

NEW COMPANIES, STATUTORY RETURNS, MORTGAGES & CHARGES, &c.

NEW COMPANIES.

INGLEBY & CO. (LTD.) (117,463.)—Reg. Aug. 30, capital £10,000 in £1 shares, to take over the business of electrical and general engineers carried on by J. C. B. Ingleby, H. S. Ingleby and E. C. Ingleby at Leeds. Private company. First directors: J. C. B. Ingleby, H. S. Ingleby and E. C. Ingleby. Reg. office: Elland-road, Leeds.

PHŒNIX TELEPHONE & ELECTRIC WORKS (LTD.) (117,562.)—Reg. Sept. 6, capital £50,000 in 49,000 6 per cent. preference shares of £1 each and 11,800 ordinary A and 8,200 ordinary B shares of 1s. each, to carry on the business of manufacturers of electrical, mechanical, scientific and telephonic apparatus and appliances, &c. Private company. First directors: H. Oppenheimer (chairman and managing director), E. J. Reid and R. Tayler. Reg. office: 6, Chatsworth-road, Brondesbury, London, N.W.

STATUTORY RETURNS.

SHEERNESS DISTRICT ELECTRIC POWER & TRACTION CO. (LTD.)—Return dated June 20 gives capital £75,000 in £10 shares (2,500 preference). 5,000 ordinary and 2,473 preference shares taken up. £10 per share called up. £74,730 paid. Mortgages and charges, £15,300.

SIEMENS BROS. DYNAMO WORKS (LTD.)—In return to June 29 capital is £300,000 in £1 shares. 20,000 shares taken up. £10 per share called up on 7. £70 paid. £199,930 considered as paid on 19,993 shares. Mortgages and charges, £200,000.

TRAFFORD POWER & LIGHT SUPPLY (1902) (LTD.)—In return to June 13 capital is £80,920 in £1 shares (23,120 preference). All shares taken up. £80,920 paid. Mortgages and charges, £54,897. 11s. 1d.

VERITAS (LTD.)—According to return to July 4, capital is £210,000 in 7,000 5 per cent. cumulative first preference, 7,000 6 per cent. cumulative second preference and 6,980 ordinary shares of £10 each and 200 management shares of £1 each. 7,000 first preference, 7,000 second preference, 5,630 ordinary and 200 management shares taken up. £10 per share called up on 4,670 first preference, 7,000 second preference and 1,430 ordinary, and £1 per share on 30 management. £131,030 paid. £65,470 considered as paid on 2,330 first preference, 4,200 ordinary and 170 management. Mortgages and charges, £58,999.

MORTGAGES AND CHARGES.

ELECTRIC & GENERAL INVESTMENT CO. (LTD.)—Particulars of debentures to secure an amount not exceeding the uncalled capital (£201,500 to date), created Aug. 18, have been filed, the amount of the present issue being £22,500. Property charged: the company's undertaking and property, present and future, except uncalled capital. The debentures are issued to Mr. Emile Garcke and Mr. J. Cecil Bull, as trustees for the holders of the stock to be created by virtue of these debentures.

ENGLISH ELECTRICAL CO. (LTD.)—Issue, on Aug. 29, of £750 debentures, part of a series of which particulars have already been filed.

T. E. SMITH & CO. (LTD.)—Debenture, dated Aug. 29, to secure £50, charged on the company's undertaking and property, present and future, including uncalled capital. Holder: Mrs. M. Smith, 7, Cavendish-street, Keighley.

CITY NOTES.

MEMORANDA (Sept. 14).—Bank rate 3 per cent. (since March 9, 1911.) Price of silver, 24½d. per oz. Consols 77⅜—77⅝ for money; 77½—77¾ for account. Consols Pay Day, Oct. 5; Stock and Shares Continuation Days, Sept. 26 and Oct. 10; Ticket Days, Sept. 27 and Oct. 11; Pay Days, Sept. 28 and Oct. 12; Mining Shares Carry Over Day, Sept. 25.

PRICES OF METALS (London).—*Copper*, cash, 55⅛; three months, 56½. *Lead*, English, 14½—15⅛; Foreign, 14⅛—14½. *Spelter*, 27¼—27⅝. *Tin*, English, 185—186; Foreign, cash, 180; three months, 177¾. *Iron*, Cleveland, cash, 46/9, three months, 47/6.

BRITISH INSULATED & HELSBY CABLES (LTD.)—The directors have declared an interim dividend on the ordinary shares for the half-year ended June 30 at the rate of 8 per cent. per annum.

CANADIAN GENERAL ELECTRIC CO.—The directors have declared a quarterly dividend of 1¾ per cent. on the common stock for the three months to 30th inst. (at the rate of 7 per cent.). A half-yearly dividend of 3½ per cent. for the six months ending 30th inst. (at the rate of 7 per cent.) has been declared on the preferred stock.

DIRECT WEST INDIA CABLE CO. (LTD.)—At the meeting on Wednesday it was reported that the net result of the year's working was an available balance of £6,323. 6s. 10d., compared with £4,530. 15s. 3d. for the year ended June 30, 1910. An interim dividend of 3 per cent. (tax free) had already been paid, and it was decided to make a further equal payment, leaving £4,523. 6s. 10d. to be carried forward. The balance to credit of revenue account, which was last year £32,626. 0s. 5d., has been debited with £900 applied to dividend, and credited with £4,523. 6s. 10d. surplus revenue of the past year, and it now stands at £36,249. 7s. 3d.

DUMBARTON BURGH & COUNTY TRAMWAYS CO. (LTD)—At the meeting last week the chairman (Mr. Geo. Balfour, M.I.E.E.) stated that the traffic receipts were fully £1,000 in excess of the receipts for the preceding year. Since October the receipts had shown satisfactory increase, and the improvements appear likely to be maintained.

HALIFAX & BERMUDAS CABLE CO. (LTD.)—The directors' report for the year ended June 30 was adopted at the meeting on Wednesday. The net result of the year's working was an available balance of £8,168. 6s. 2d., compared with £5,737. 11s. for 1910. An interim dividend of 2½ per cent. (tax free) had already been paid, and it was decided to make a further equal payment, leaving £5,668. 6s. 2d. to be carried forward. The balance to credit of revenue account, which was last year £21,676. 16s. 2d., has been debited with £1,250 applied to dividend, and credited with £5,668. 6s. 2d. surplus revenue of past year, and it now stands at £26,095. 2s. 4d. The company's cable has worked efficiently. The subsidy from the Imperial Government of £8,100 per annum expired on July 14, 1910.

MANILA ELECTRIC RAILROAD & LIGHTING CORPN.—A dividend is announced of 1¼ per cent. ($1.25 per share) for the quarter ending Sept. 30.

NATIONAL ELECTRIC CONSTRUCTION CO. (LTD.)—Mr. L. B. Schlesinger stated at the meeting on Wednesday that they were making arrangements for securing a contract for the construction of an electric railway on the Continent, the first part of which would cost £150,000. They had another contract on hand for £450,000, and various smaller contracts. The undertakings in which they were interested in this country were making slow progress. Rhondda Tramways Syndicate were paying 6 per cent. Mexborough and Swinton Tramways showed increased receipts: Torquay Tramways (having adopted the overhead system) showed largely reduced costs and better prospects. The Musselburgh and District Company was paying 6 per cent. on the preference shares, and Dewsbury and Ossett tramways showed a profit of £261, compared with a loss of £820 last year. The gross profit for the past year of the National Electric Company was £11,456.

NATIONAL ELECTRIC CONSTRUCTION CO. (LTD.)—The directors' report for the year ended Dec. 31, 1910, states that the available balance is £7,350, of which the directors recommend that £1,550 be transferred to debenture redemption fund and £644 to depreciation on free-wired installations, &c., carrying forward £5,156.

UNITED ELECTRIC CAR CO. (LTD.)—The report for the year ended June 30 states that during the year there had been a great stagnation in the car-building trade of the country. The works are now well employed. After paying debenture interest (£2,366) and charging £5,886 for depreciation, the profit is £4,420, added to £4,061 from last year, making £8,481. The Preference dividend to Dec. 31 absorbed £3,000, leaving £5,481. The directors recommend payment of balance preference dividend (less tax) (£3,000) and to carry forward £2,481. The Hadley and Trafford Park works have been disposed of. The directors regret that a loss of £46,17[illegible] has been incurred, which they propose shall be written off.

The Olympia Electrical Exhibition 177
Olympics..... 184

NOTES.

Steam v. Internal Combustion Engines.

ONE of the most interesting discussions that took place at the recent meeting of the British Association was on the relative merits of steam plant, suction gas plant and Diesel engines. Three Papers were read in which the claims of the advocates of each type of plant were clearly set forth; an abstract of the Paper by Mr. W. A. TOOKEY on suction gas plant appeared in our last issue, whilst elsewhere in the present issue will be found abstracts of the Papers contributed by Mr. W. T. MARSHALL and by Mr. C. DAY on "Over-type Superheated Steam Engines" and "The Diesel Oil Engine" respectively. These three Papers are more than usually interesting since they give the results of tests carried out over considerable periods on plant under normal working conditions.

THE low fuel consumption of internal-combustion engines has, as Mr. MARSHALL points out, undoubtedly stimulated the manufacturers of steam engines to perfect more efficient steam plant for small installations. The "locomobile"—to use the name which is better known abroad—is to some extent the result of this competition. With this plant a fuel consumption of from 1·2 lb. to 1·4 lb. per brake horse-power-hour is recorded by Mr. MARSHALL, but a consumption as low as 0·9 lb. per brake horse-power-hour has, we understand, been obtained with the Wolf locomobile. This last-mentioned figure is certainly comparable with the best records of gas plant, with which Mr. TOOKEY mentions that 0·7 lb. to 0·85 lb. per brake horse-power-hour is regularly obtained in normal working. Although Mr. TOOKEY quotes a number of instances to illustrate the low cost of maintenance and the reliability of suction gas plants, we think that engineers will not yet be convinced that in these respects suction gas plant is as satisfactory as steam plant, whilst capital charges will frequently have more effect than that allowed by the author.

WITH regard to Mr. DAY's Paper on Diesel engines, the author mentions the importance of not paying too much attention to manufacturers' guarantees of fuel consumption, owing to the different conditions obtaining in practice. We think, however, that the Table which he gives, based on the published records of electric supply stations, is also liable to be misleading. Much of the steam plant on which this Table is based is probably inefficient and out of date. That the Diesel plant considered is probably of more recent installation is shown by the figures for repairs and maintenance, this item for steam plant being stated as 0·26d. per unit, as against 0·07d. for Diesel stations and 0·24d. for gas plants. The desirability, if not necessity, of employing skilled labour in running Diesel plant may sometimes prove a disadvantage, but there is no doubt that this engine shows to advantage in the case of stations with a poor load factor, and in which the stand-by losses are heavy. Electrical engineers, however, are hoping that such cases will become comparatively rare in the future.

The Exhibition.

As we go to press we are on the eve of the opening of the second Electrical Exhibition held in London within the past 10 years. During the four weeks in which it remains

Digitized by Google

open the people of the Metropolis and the Home Counties (at any rate) will have opportunities of inspecting the latest electrical devices for making homes brighter and cleaner and for rendering commerce and industry more efficient. We are glad to see that the British Electrical Allied Manufacturers' Association, to use its newly adopted title, has made the Exhibition an essentially popular one. An exclusively trade exhibition would have done little or no good at the present time. On the other hand, the industry is not sufficiently well grouped to run a show which would appeal solely to the public and make no demands upon the trade. In the present Exhibition we have a happy combination of the two. There is very little heavy machinery, plenty of "apparatus and accessories," and an abundance of lamps, fittings, small motors, cookers, heaters, radiators, cigar lighters, &c. This combination represents in their proper proportions the elements needed to make up a combined trade and popular Exhibition.

FROM a preliminary inspection of the stands we can vouch for a full measure of completion by the time of the opening to-morrow. The body of the huge hall is well filled; in fact, almost too well, for the gangways and stands seem narrower than at the last show. The gallery is about half filled and is devoted to the smaller and lighter exhibits. The electric cooking demonstrations in particular should attract special notice, and we hope that the daily press will be given facilities for witnessing these and for providing their readers with intelligent copy regarding electric cooking generally. The large sums spent by the London gas companies in newspaper advertising have resulted in the publication of well-written articles on gas cooking and heating, and the benefits of these disquisitions are now being reaped by those fundamentally responsible for them. We ourselves are dealing with the Exhibition in the columns of the Commercial and Industrial Supplement and we refer our readers to this section in the present and succeeding issues for a fully illustrated description of the exhibits. In particular we would direct attention to the map of Olympia and guide to the exhibits which occupies the centre pages of the Supplement this week.

WE gather from the Executive Committee that up to the present moment there has been practically no attempt on the part of company and municipal supply authorities to purchase tickets for the Exhibition in the same way as was done at Manchester. It may be that these public bodies are slow to take action in matters of this sort. There is plenty of time; but we may voice a reminder that co-operation of this character is essentially practical and will result in undoubted advantage to electricity supply both in London and the Provinces. The public will need to be specially attracted to the Exhibition, and the wise distribution of tickets among present and prospective consumers will materially assist in popularising what is, after all, a popular electrical show.

Cable Interruptions and Repairs.

	Date of Interruption.	Date of Repair.
Assab—Perim	July 8, 1909 ...	—
Latakia—Palura	May 26, 1910 ...	—
Zanzibar—Mombasa	July 11, 1911 ...	—
Sabang—Koetaradja	Aug. 18, 1911 ...	Sept. 5, 1911
Kotonou—Grand Bassam	Aug. 23, 1911 ...	—
San Thiago—Bathurst	Sept. 4. 1911 ...	—
Bathurst—Sierra Leone	Sept. 4, 1911 ...	—

Mr. Edison.—Mr. Thomas Alva Edison, who with his family is continuing his Continental tour, has been féted in Vienna and Budapest, and, according to the Austrian papers, is now journeying onwards to Switzerland, Holland and France.

University of Christiania.—In celebration of its jubilee this University recently conferred a number of honorary degrees. Among those so honoured were Sir Wm. Ramsay, F.R.S., Sir J. J. Thomson, F.R.S., and Dr. H. A. Miers, F.R.S.

New Electro-Steel Works on Tyneside.—The "Engineer" mentions that the Electro-Flex Steel Co. have acquired a site adjoining the new Dunston power station of the Newcastle-on-Tyne Electric Supply Co., and propose to manufacture steel entirely by means of electric furnaces. The initial installation is to consist of two 200-kw. Stassano furnaces.

The B.A. Report on Electrical Measurements.—Mr. A. P. Trotter informs us that his name has been attached to the report of the British Association Committee on Practical Standards for Electrical Measurements without his authority, and doubtless as the result of a mistake. But it compels him to state that he withdrew from the Committee in July, 1910, because he strongly disagreed with some of their resolutions, and with the mode in which their business was conducted.

Popular Science.—During the last week or two our daily contemporaries have been in ecstasies about the wireless telephony experiments of Mr. H. Grindell Matthews. The articles on such occasions are generally amusing, and for the benefit of our readers we cannot refrain from quoting the following from the "Daily Chronicle":—

> The man who has made the discovery is a young scientist, Mr. H. Grindell Matthews, who has been so richly endowed as an inventive genius that he was the other day made a Member of the Royal Institution at an earlier age than that ever before recorded in the membership rolls of the institution . . . The invention is so far-reaching in its possibilities of useful application that its author has been strongly advised to compete for the coveted Nobel prize, and he has decided to do so next year.

Electric Power and the Farmer.—A pamphlet recently published by Dr. L. C. Wolff in Germany, under the title of "Der Landwirtschaft und die Uberlandzentrale" contains an indictment of the recent policy of erecting large generating stations principally for agricultural purposes. It is reported that millions of marks have been lost in these schemes. The Crottorf station, which was erected 10 years ago for supplying current to 10 towns, has inflicted a capital loss of £140,000 and a loss of interest of £20,000 on its shareholders. The power stations at Wandersleben, Blankenheim and Floh are in a state of bankruptcy. The stations at Birnbaum and Meseritz have had to quadruple their capital, and the station at Derenburg has had to increase the original sum eight times. These facts are not, however, considered to show that these stations are a failure, for wherever they are properly engineered and managed they will eventually become valuable components of the nation's wealth. The large manufacturers argue that it is only by such schemes that the way can be paved for the electrification of all main railway lines. They maintain that as soon as railways, factories and farmers are counted amongst the consumers of such power stations a good return will be received from the capital invested. The condition of these undertakings, however, at present seems to be not unlike that of many of our "power" companies.

Current Topics.

Subjects of current interest dealt with in this issue include the following:—

Dr. R. A. Houstoun continues his series of "Studies in Light Production." The title of his article in the present issue is "Flames."

Mr. W. Dubilier contributes an article on "An Improved Wireless Telephone Transmitter."

The following Papers read at the recent meeting of the British Association will be found in the present issue: "The Single-phase Repulsion Motor," by Mr. T. F. Wall; "Economical and Reliable Power Generation by Over-type Superheated Steam Engines," by Mr. W. J. Marshall; "The Diesel Engine," by Mr. C. Day; "A Friction Permeameter," by Mr. W. H. Murdoch; "Smoke Abatement," by Dr. J. S. Owens.

Digitized by Google

We describe a new form of flexible steel mast known as the Fontana Mast, which has been introduced in Germany, and is suitable for wireless telegraphy.

We describe the electrical equipment of the Craighead and Bothwell Collieries.

The Electrical Exhibition at Olympia opens to-morrow. An account of some of the exhibits will be found in our "Commercial and Industrial Supplement."

An abstract is given of the report of Sir F. Oppenheimer (British Consul-General) on the trade of Germany in the past year.

Companies' Meetings and Reports.—At the meeting of the Yorkshire Electric Power Co., on Tuesday, particulars were given of the progress made by the Company during the half-year, many additional customers having been connected to the mains.

A report of the meeting of the United Electric Car Co. appears in another column.

The directors' report of Cleveland & Durham Electric Power (Ltd.), which gives information as to the Company's progress during the past year, states that arrangements have been made to erect further waste heat generating stations.

The directors' report of the Direct United States Cable Co. is also given.

OBITUARY.

P. A. EDMUNDSON.—We regret to record the death of Mr. P. A. Edmundson, electrical engineer, in the service of the Cornwall Electric Power Co., who was drowned while bathing at Hayle on the 9th inst.. Deceased, who was only 28 years of age, was a native of Dublin.

A. SCHWIEGER.—The death is announced of Herr Adolph Schwieger, a director of the Siemens Schuckert and Siemens Halske works, and a pioneer of electric railways. The deceased was 66 years of age.

PERSONAL NOTES.

Mr. J. H. Butters, B.Sc., A.M.I.E.E., has been appointed chief engineer of the new Hydro-Electric Power & Metallurgical Co. (Ltd.), of Tasmania, and manager of their hydro-electric supply department.

Mr. Butters, who was educated at Hartley University College, and is a graduate of the University of London, served as apprentice with Thornycroft & Co., leaving them to join Siemens Bros. Dynamo Works, of London and Stafford. Whilst with the latter Mr. Butters held the position of designing engineer, and was subsequently in charge of the estimating and design department at the Stafford works, being later transferred to the head office as central station and power engineer. Two years ago he was appointed engineer of the firm's Australasian branch, which position he has now resigned to take up his new appointment. Mr. Butters is proceeding immediately to Tasmania to prepare specifications, &c., for the machinery which will be necessary to carry on the new company's work.

Mr. James Strachan has resigned the position of works manager, which he has held for the last three years with Messrs. Tetley & Co., Salford, and is now manager of the works of Salford Electrical Instruments (Ltd.), North George-street, Salford.

Mr. R. J. Rosser, A.M.I.E.E., Assistant City Electrical Engineer of Cape Town, left for England in the s.s. "Buluwayo" on Sept. 4 for a six month's holiday. He will be visiting the Electrical Exhibition at Olympia and will afterwards proceed to the Continent of Europe and the United States on a general tour of inspection.

APPOINTMENTS VACANT AND FILLED.

Test-room assistants, for adjusting and calibrating a.c. and d.c. instruments, are wanted; also assistants for photometry. See advertisement.

A switchboard attendant is required for South Africa (h.t. three-phase system). Salary £300 per annum. See advertisement.

Swindon Corporation require an assistant electrical and mechanical engineer for their electricity and tramways departments. Salary £130, rising to £180. Applications to the Town Clerk by Sept. 23.

An assistant lecturer in physics is required at St. Andrews University. Stipend £100 per annum. Applications to the Secretary.

A firm in the Midlands require an assistant tester, well up in testing a.c. and d.c. machinery. See advertisement.

Mr. Philip Kemp, M.Sc.Tech., has been appointed lecturer in electrical engineering at East London College (University of London) in succession to Mr. L. Murphy, who has resigned to take up the position of managing engineer to the Perry Barr Fan Works, Birmingham.

Mr. Kemp, after a distinguished career at Manchester Municipal School of Technology, spent two years at Messrs. Mather & Platt's works in the testing department, designing room and drawing office. Since then he has had two years of teaching experience in electrical design and laboratory classes under Prof. Schwartz. He was awarded in 1910 the "Joule" medal for a paper on "Some Thermo-dynamic Properties of Rubber," and is joint author of a Paper printed in the "Journal" of the I.E.E. on "The High-Tension Spark Discharge in Air."

Mr. Harry Pulling, superintendent of the mechanical and electrical department of Accrington Corporation tramways, has been appointed manager of the tramways at a salary of £200 per annum, in succession to Mr. Jas. Wilson, who has retired.

Mr. G. W. Cansdell Hirst has been appointed demonstrator in electrical engineering at Sydney (N. S. W.) Technical College.

INSTITUTIONS AND SOCIETIES.

Junior Institution of Engineers.—Mr. G. Marconi, D.Sc., has been elected president of this Institution in succession to Sir J. J. Thomson, F.R.S.

Iron and Steel Institute.—The proposed Italian meeting for which arrangements had been announced has had to be abandoned owing to numerous withdrawals, during the last week or two, of members who had intended to be present. The falling-off is attributed to labour conditions in this country, the political situation in Europe, and rumours as to the prevalence of cholera in Italy. As the statutory requirements of the Charter of the Institute necessitate a meeting being held in the autumn, arrangements have been made to hold a meeting at the Institution of Civil Engineers on Thursday, October 5, when the Papers down for reading at the Turin meeting will be considered.

EDUCATIONAL NOTICES.

University of London, University College.—The new session commences on Monday, Oct. 2. There are complete courses of study, extending over three years, in mechanical, electrical, civil and municipal engineering. Particulars from the secretary, Mr. Walter W. Seton, M.A., Gower-street, W.C.

University of London, King's College.—Complete courses of study, extending over three or four years, are provided in civil, mechanical and electrical engineering for engineering degrees of the University of London, and for the diploma and certificate of the college.

The four-years' course provides, in addition to the academic training, opportunity for practical training in works. Special advanced lectures and courses in civil and mechanical as well as electrical engineering, will commence in October. Among the lecturers in electrical engineering are Mr. W. H. Patchell, who will deal with "Electric Generating Stations" and "The Application of Electric Power to Mines and Heavy Industries"; Mr. F. Lydall, who will lecture on "Electric Traction, Direct and Alternating Current"; and Mr. Wm. Brew, who will deal with "Electric Lighting." Detailed syllabus and further particulars may be obtained from the Secretary, King's College, Strand, London, W.C.

University of Edinburgh.—The next session opens on Oct. 10. The University provides complete courses in civil, mechanical and electrical engineering, qualifying for the degree of B.Sc. in engineering, and extending over a period of three years. Particulars from the Matriculation Office, The University, Edinburgh.

University of Manchester.—Complete courses of study, extending over three years, are arranged for the University degrees in civil, mechanical and electrical engineering. The session commences on Oct. 2.

University of Durham.—Armstrong College, Newcastle-upon-Tyne.—The 1911-12 session commences Sept. 25. Courses of instruction are provided in mechanical, marine, civil and electrical engineering, naval architecture, mining, metallurgy, agriculture, pure science, arts and letters. Particulars from the secretary, Mr. F. H. Pruen, M.A.

The Calendar for the 1911-12 session has been issued, and contains particulars of the courses of instruction in engineering, physics, mathematics, chemistry, metallurgy, &c. Good provision is made for evening classes and there is also suitable accommodation for practical work and research.

Goldsmiths' College (University of London).—At this college complete evening courses of instruction are provided in mechanical, electrical and constructional engineering, land surveying, fitting and machining, pattern-making and smithing. Students are prepared for the London University degree of B.Sc. in engineering, for the examinations of the Institution of Civil Engineers, Board of Educa-

Digitized by Google

tion, and City and Guilds of London Institute, &c. Particulars from the Warden of the College, New Cross, S.E. The new session commences on Monday, Sept. 25.

University College of North Wales.—At this college a systematic course of instruction in electrical measurements and practical electricity is provided for students proposing to enter the electrical engineering profession. The session commences in October.

Borough Polytechnic Institute.—A four years' course of instruction in electrotechnics is provided at this Institute. There are also classes in electric wiremen's work, and elementary and advanced courses in electrical design and workshop drawing. The head of the department is Mr. John Henderson, D.Sc., F.R.S.E., A.M.I.E.E. Prospectuses from the Principal, Mr. C. T. Millis, Borough-road, S.E. The session begins on 25th inst.

Northampton Polytechnic Institute, Clerkenwell, London.—The full day courses in the theory and practice of mechanical and electrical engineering and in electro-chemistry will commence on Oct. 2, and entrance examinations will take place on Sept. 27 and 28, at which five entrance scholarships will be offered. The courses for mechanical and electrical engineering include periods spent in commercial workshops, and extend over four years, and they also prepare for the degree of B.Sc. in engineering of the University of London. There are also full and partial day courses in technical optics. Particulars from the Principal, Dr. R. Mullineux Walmsley.

We have received a copy of the "Announcements" for the session 1911-12 and among the new developments may be noted:—

In the electrical engineering department the new generating station, which was opened by the chairman of London County Council last winter, is now available for the instruction of senior students in both day and evening courses. The equipment of the station (which was described at the time of the opening in THE ELECTRICIAN) is very complete in all details of the generation and distribution of continuous and alternating currents. In the mechanical engineering department the equipment for experimental work in aeronautics has been much increased and it is hoped that valuable work of a research character will be done by the senior students during the winter. In other departments various additions have also been made.

In the evening classes an important series of lectures is being given jointly by the Electrical Engineering, Technical Chemistry and Technical Optics Departments on Illuminating Engineering. These lectures will be given by various specialists in the different sections of the subject and form an important development in the work of the Polytechnic. Changes have been made in the telegraphy and telephony courses in the electrical engineering department to meet the changes which are taking place outside. The position is complicated by the abolition of the stage I. examinations of the Board of Education which have hitherto been required by the Post Office authorities as one of the conditions for certain departmental advances. These authorities have not yet decided as to what shall take the place of the Board of Education examinations, but students are strongly advised by their senior officers to continue their studies on the old lines. In submarine cable work and in radio-telegraphy the advanced classes are being continued and developed. In the mechanical engineering department, to meet the growing development, the course in aeronautical engineering has been divided into two courses, one being the advanced engineering course of previous sessions, and the other a more advanced course for senior students. In technical optics and in technical chemistry some of the evening courses have been remodelled to adapt them more to the requirements of students. Throughout there have been a fair number of changes in the various syllabuses bringing them up to date, and the educational work is being carried on along the lines which have been found so successful in previous years. New departures are made in the day work of the technical chemistry and of the horological departments by the institution of morning classes for apprentices in workshops. In these classes students, all of whom are engaged in commercial workshops, are in attendance from 9 a.m. to 1 p.m. and spend the afternoons in their employers' workshops.

Battersea Polytechnic (London, S.W.).—The new session commences on Monday, 25th inst. There are complete day college courses in civil, mechanical and electrical engineering, extending over three or four years. These courses are suitable for preparing for the B.Sc. (Eng.) of the University of London, the Associateship examination of the Institution of Civil Engineers, &c. There are also evening classes in electrical technology, electrical design and power distribution, theory of machines, hydraulics, heat engines, strength of materials, &c. Further particulars from the Secretary.

A course of 12 lectures, six during the first term and six after Christmas, will be given on "Illuminating Engineering." On Oct. 17 and 24 Prof. J. T. Morris will lecture on "Electric Lighting;" on Oct. 31 and Nov. 7. Mr. J. G. Clarke will lecture on "Gas Lighting." Mr. E. Scott Snell will deal with "Oil, Petrol-air and Acetylene Gas" on Nov. 14, and Dr. W. J. Ettles will give a lecture on "Illumination and the Eye" on Nov. 21. The remaining six lectures (to be delivered in the second term) will deal with the Measurement of Light and Practical Problems in Illumination and will be delivered by Mr. J. S. Dow, B.Sc., Fee for full course, 7s. 6d.

South-Western Polytechnic Institute.—This institute provides a complete three-years' course, leading to a diploma or university degree, in electrical engineering. A four-years' course is held in the evening. Separate courses of lectures and practical work are given in elementary, intermediate and advanced electrical engineering, electrical design, a.c. and polyphase currents, wiring and fitting, &c.

Mr. A. J. Makower, M.A., M.I.E.E., is head of the electrical engineering department, and he is assisted by a competent staff of teachers. The course of instruction is suitable for students, either before or after gaining practical experience in workshops. The institute is lighted by its own generators which have been specially arranged to allow of complete tests to be carried out from time to time by students. Those who take the complete electrical course will be instructed in practical wiring and the making of joints, and the practical work in the laboratory is made to illustrate the principles given in the lectures as far as possible. Ample provision is also made for evening students in the department, and complete courses of three evenings per week for four years are arranged for those desirous of gaining a thorough training in the principles of the theory of electrical engineering, and of those subjects that are intimately connected therewith. A prospectus, containing full particulars of day and evening classes, may be obtained (post free 3½d.) from the Secretary Manresa-road, Chelsea, London, S.W.

East London College (University of London).—In the Faculty of Engineering complete courses of instruction are provided in engineering subjects, including civil, mechanical and electrical engineering. There are special facilities for apprentices on the sandwich system. The fee for the session is 10 guineas. Further particulars from the Registrar or from the principal, Mr. J. L. S. Hatton, M.A.

Sir John Cass Technical Institute.—During the Autmun and Lent terms special courses of instruction will be given at this college in "Engineering Metals and Alloys," by Mr. Wesley J. Lambert (there will be 24 lectures, followed by suitable work, commencing Oct. 5), and on "Liquid, Gaseous and Solid Fuel," by Mr. J. S. Brame (20 lectures, commencing Oct. 16). A detailed syllabus of the course may be obtained from the offices of the Institute, or by letter to the Principal, Jewry-street, Aldgate, London, E.C.

Northern Polytechnic Institute, London.—We have received a copy of the prospectus for the 1911-1912 session. There are day and evening classes in engineering, physics, mathematics, chemistry, &c.

ARRANGEMENTS FOR THE WEEK.

SATURDAY, September 23rd.

ELECTRICAL EXHIBITION AT OLYMPIA.

2 p.m. Formal opening of the Exhibition, by Sir William Preece, K.C.B., F.R.S.

TUESDAY, September 26th.

JUNIOR INSTITUTION OF ENGINEERS.

6:30 p.m. Visit to the Electrical Exhibition at Olympia.

MUNICIPAL TRAMWAYS ASSOCIATION.

WEDNESDAY, September 27th.

10:30 a.m. Annual Conference at Glasgow. Reception by the Lord Provost and the Convener and Members of the Glasgow Tramways Committee, in the Council Chamber.

11 a.m. Presidential Address by Mr. J. Dalrymple (General Manager, Glasgow Corporation Tramways); and Paper on "The Common Good of the City of Glasgow, its Origin, History and Present Position in Relation to the Tramways Undertaking," by Councillor W. Nelson (Sub-convener of the Tramways Committee.)

3:30 p.m. Paper on "Tramways Finances and Policy," by Councillor J. H. Rodgers (Chairman of the Newcastle-upon-Tyne Corporation Tramways Committee). Discussion to be opened by Mr. W. J. Squires, of the London County Council.

7:30 p.m. Dinner in the City Chambers.

THURSDAY, September 28th.

10:30 a.m. Conference in the Hall at Newlands Depot. Paper on "Tramcar Meters," by Messrs. R. G. and J. G. Cunliffe (Technical Assistants, Manchester Corporation Tramways). Discussion on this Paper to be opened by Mr. T. B. Goodger (General Manager, Croydon Corporation Tramways) and Mr. W. Clough (General Manager, Bury Corporation Tramways). Report on "Tramway Track: Methods of Construction and Maintenance," by the Representatives of the Glasgow, Manchester and Leeds Corporation Tramways.

2:30 p.m. Annual Business Meeting in the Hall at Newlands Depot.

3:15 p.m. Visit to Rouken Glen.

7:45 p.m. Association Dinner in the Grosvenor Restaurant, Gordon-street.

FRIDAY, September 29th.

11 a.m. Excursion to Ayr and the land of Burns (arriving back at Glasgow at 7:20 p.m.).

THE LONDON ELECTRICAL ENGINEERS.

Officer Commanding, Col. H. M. Leaf.

The following orders have been issued:—

Head-quarters will be closed for instruction, but will be open for other work as under until further orders:—

Monday to Friday, 10 a.m. to 4 p.m.
Saturday, 10 a.m. to 12 noon.

Digitized by Google

THE SINGLE-PHASE REPULSION MOTOR.*

BY THOMAS F. WALL, M.SC., M.ENG.

Summary.—In the first part of this Paper expressions are deduced for the E.M.F.s induced in the stator and rotor windings, and curves are given which enable some of these E.M.F.s to be rapidly determined for any value of the displacement of the rotor brushes from the stator axis. In the second part of the Paper the results previously obtained are employed in developing the theory of the repulsion motor. A series of simultaneous equations enable expressions to be obtained for the speed, stator current, power factor and power of the motor. In the third part of the Paper the results of some tests on a 6 B.H.P. motor are given, and the values of the stator current, power factor and speed are shown to be in agreement with the theory. Finally, a method of calculating the open circuit characteristic of a single-phase motor is given.

In dealing with the subject of alternating-current commutator motors it is not easy to adapt the methods used for other types of alternating-current machinery, since the commutator motor partakes partly of the nature of a transformer and partly of the nature of an alternator, and for this reason, in evolving a theory of these machines it is of the greatest importance that the methods adopted should be as simple as possible in order that the subject, which is intrinsically of considerable complexity, may not be made more so by complicated methods of treatment. In order that the practical engineer may have a clear idea of the physical aspect of the subject, it is most desirable that the methods of design should not involve any other ideas than those usually employed in the design of transformers and electrical machines. The subject has been dealt with by several writers, notably Steinmetz,† Bragstad,‡ and Fischer-Hinnen.§ The treatment of Steinmetz and Bragstad involves the use of the symbolic method, and assumes sinusoidal distribution of the flux in the air-gap. Although the symbolic method leads to a singularly elegant solution, it is not at present familiar to the practical engineer. Moreover, the assumption of sinusoidal flux distribution is not very satisfactory. Fischer-Hinnen has shown how the vector diagram may be drawn for one position of the rotor brushes, but the solution is not a general one.

In the following treatment the plain repulsion motor has been dealt with, and it is hoped that the results obtained may be of immediate use to the designer. Experimental evidence as to the accuracy which may be expected from the theory is given, tests having been made on a motor designed for 6 B.H.P. at 50 cycles 120 volts.

The Déri modification of the plain repulsion motor may be considered as a special case, and can be dealt with quite easily by slight modifications of the formulæ deduced in the Paper.

The only assumptions made in the following development are that the iron losses and commutation effects are small and that the permeability of the magnetic circuit is constant. That the influence of the circulating currents in the coils undergoing commutation is extremely small is evident from Fig. 20.

No assumption as to sinusoidal flux distribution in the air-gap has been made, the triangular or trapezoidal flux distribution, as the case may be, having been dealt with throughout.

PART I.

Before developing the author's theory of the repulsion motor, formulæ for the following will be established :—

1. The E.M.F. induced in the stator winding due to an alternating current in that winding.
2. The E.M.F. induced in the rotor winding due to an alternating current in the stator winding.
3. The E.M.F. induced in the rotor winding when rotating in the field due to an alternating current in the stator winding.
4. The E.M.F. induced in the stator winding due to an alternating current in the rotor winding.
5. The E.M.F. induced in the rotor winding due to an alternating current in that winding.

Now, since we can write for the case of a sine wave form of applied pressure

Effective E.M.F. = 4·44 × frequency × maximum flux linkages × 10^{-8}

(the flux linkages being the sum of the products—flux × number of turns linked—taken for all the turns), expressions for the maximum flux linkages in the five cases stated above may be at once deduced from the expressions for the E.M.F.s.

It is quite justifiable to assume a sine wave form for the applied pressure (and consequently for the corresponding induced flux), since in practice a sine wave form is the standard for alternating current generators.

In establishing the above five expressions no assumption will be made as to sinusoidal distribution of flux in the air-gap space, but as far as possible the actual flux distribution will be considered.

Fig. 1 represents diagrammatically a plain repulsion motor having two poles. The axis of the stator winding is represented by the line AB, and CD represents the brushes, which are short-circuited, and thus forms the axis of the rotor winding. (In what follows the letters A, B, C, D refer to points on the rotor or the stator, according to the member considered.) The angle between the axes of the stator and rotor windings respectively is represented by θ, and $2a$ is the angle subtended by the unwound portion of the stator periphery.

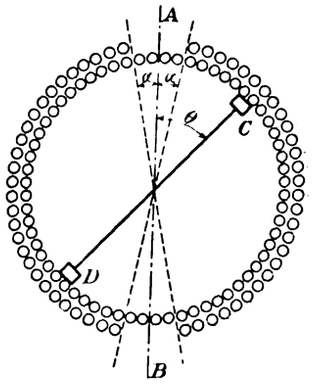

FIG. 1.

If a current be led into the stator winding, and if we suppose for a moment that both stator and rotor have smooth peripheries, the flux distribution in the air-gap will be represented by Fig. 2 for an indefinitely large number of stator conductors. As a matter of fact, both stator and rotor will be slotted in practice, and the number of conductors will not be indefinitely large. Suppose that only the stator be slotted, then the flux distribution may be represented in some such way as is given by the full line in Fig. 2*a*. The value of the flux linkages, however, given by the full line in Fig. 2*a* will be the

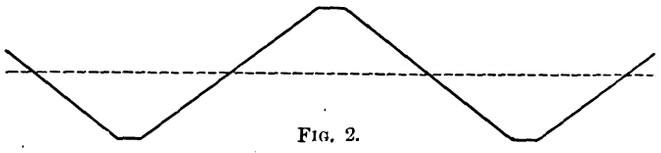

FIG. 2.

same as the value obtained by considering the distribution to be as shown by the dotted line in Fig. 2*a*, diminished by some constant which is independent of the magnitude of the current in the winding. The effect of slotting the rotor core may be similarly dealt with by introducing a second constant. These two constants may be combined in a single constant,* a knowledge of which enables the actual flux linkages to be obtained by considering the stator and rotor as having smooth cores, and the flux distribution as shown in Fig. 2.

FIG. 2*a*.

Let r be the mean radius of the air-gap measured in centimetres.

l be the mean effective axial length† of the stator and rotor cores measured in centimetres.

w_1 be the number of conductors per centimetre length of stator periphery.

w_2 be the number of conductors per centimetre length of rotor periphery.

$B_{max.}$ be the maximum flux-density in the air-gap *as regards both time and space*. That is to say, if the flux distribution be represented by Fig. 3 *when the stator current is a maximum*, then B_{max} will be given by the ordinate AA′.

$B_{max.}$ be the maximum flux-density in the air-gap as regards space only—that is, the density *at any instant* at the points A or C (Fig. 1).

The maximum value of the flux-density at any point, X, distant x cm. from R, is

$$= B_{max} 2x/r(\pi - 2a), \text{ for a two-pole machine.}$$

If the machine have P pairs of poles, and π and a be measured in electrical degrees, then the flux-density at X will be

$$= B_{max} 2x\mathrm{P}/r(\pi-2a).$$

The effective E.M.F. induced between the stator terminals will be

$$= 2\mathrm{P}\left[\int_{x=o}^{x=r(\pi/2-a)/\mathrm{P}} 2\bar{B}_x l w_1 x 4{\cdot}44\,\nu\,10^{-8}\,dx + 2\bar{B}_{max}\, l\frac{a}{\mathrm{P}} r w_1 \frac{(\pi/2-a)}{\mathrm{P}} r\, 4{\cdot}44\,\nu\,10^{-8}\right]$$

for frequency ν, if all the conductors are in series.

If the conductors be arranged in p_{2s} sets in parallel, this expression must be divided by p_{2s}.

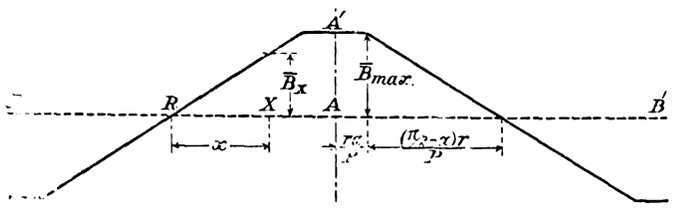

FIG. 3.

Simplifying this expression, we get :—

The effective E.M.F. induced in the stator winding due to a current in that winding is

$$= \frac{1}{3\mathrm{P}p_{2s}} 4{\cdot}44\,\nu\,\bar{B}_{max} l w_1 r^2(\pi-2a)(\pi+4a)10^{-8} \quad . \quad . \quad . \quad (1)$$

or, dividing this expression by $4{\cdot}44\,\nu\,10^{-8}$, we get :—

The maximum flux linkages of the stator winding due to a current in that winding is

$$L'_s = \frac{1}{3\mathrm{P}p_{2s}} \bar{B}_{max} l w_1 r^2(\pi-2a)(\pi+4a) \quad . \quad . \quad . \quad . \quad (1a)$$

We may proceed in a somewhat similar manner in order to obtain the E.M.F. induced between the rotor brushes by the flux due to a current in the stator winding. Referring to Fig. 4, the flux distribution in the air-gap is again shown, and C and D represent the short-circuited brushes. It is clear that no E.M.F. is induced in the

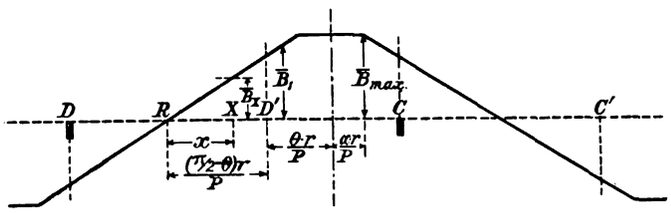

FIG. 4.

band of conductors on the rotor subtended by the angle θ on each side of the stator axis. Hence it is only the conductors contained in the bands CC' and DD' of the rotor periphery which develop an E.M.F., of which the effective value is

$$= \frac{2\mathrm{P}}{p_{2r}}\left[\int_o^{r(\pi/2-\theta)/\mathrm{P}} 2\bar{B}_x l w_2 x 4{\cdot}44\,\nu\,10^{-8}\,dx + 2\bar{B}_1 l\frac{\theta-a}{\mathrm{P}} r\, 4{\cdot}44\,\nu\,10^{-8} w_2 \frac{(\pi/2-\theta)}{\mathrm{P}} r\right.$$
$$\left. + 2\bar{B}_{max} l r\frac{a}{\mathrm{P}} 4{\cdot}44\,\nu\,10^{-8} w_2 \frac{\pi/2-\theta}{\mathrm{P}}\right],$$

in which p_{2r} represents the number of parallel paths in the rotor winding, and $\bar{B}_1$ is the mean value of the flux-density over the band of conductors $(\theta-a)r/\mathrm{P}$.

Simplifying this expression, we get :—

The effective value of the E.M.F. induced between the rotor brushes due to an alternating current in the stator winding is

$$= \frac{\mathrm{I}}{3\mathrm{P}p_{2r}} \bar{B}_{max} l w_2 4{\cdot}44\,\nu\,10^{-8} r^2\left[\pi-2\theta\right]\left[\frac{\pi^2+2\pi\theta-2\theta^2-6a^2}{\pi-2a}\right] \quad (2)$$

or, dividing by $4{\cdot}44\,\nu\,10^{-8}$, we get :—

The maximum flux linkages of the rotor winding due to a current in the stator winding is

$$L'_R = \frac{1}{3\mathrm{P}p_{2r}} \bar{B}_{max} l w_2 r^2\left[\pi-2\theta\right]\left[\frac{\pi^2+2\pi\theta-2\theta^2-6a^2}{\pi-2a}\right]. \quad (2a)$$

The expressions 2 and 2a hold if θ is equal to or greater than a. If, however, θ is less than a, we must obtain a new expression for the flux linkages. This becomes

$$= \frac{1}{3\mathrm{P}p_{2r}} \bar{B}_{max} l w_2 r^2\left[\pi^2+2\pi a-6\theta^2-2a^2\right].$$

The case of θ less than a is not of very great importance, and we shall not further consider it.

In the expression (2a) the product of the quantities in brackets may be represented by Θ_c, and has been worked out for various values of θ from 0 to $\pi/2$. Fig. 5 shows a curve connecting Θ_c and θ (assuming $a=0{\cdot}1\pi$, which is a reasonable value), but it must be remembered that this curve is only applicable for values of θ between a and $\pi-a$.

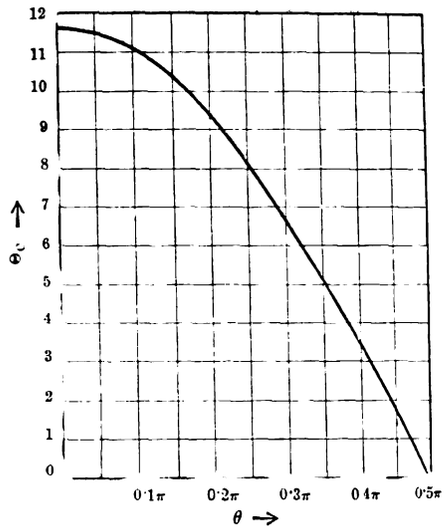

FIG. 5.

In order to deduce the E.M.F. induced between the rotor brushes when the rotor is revolving in the field due to an alternating current in the stator winding, we may proceed as follows :—

The effective E.M.F. due to rotation is

$$= \frac{\mathrm{N}Z_2 n 2\mathrm{P}}{\sqrt{2}\cdot 60 p_{2r} 10^8} \text{ volts},$$

N being the maximum flux threading the short-circuited coil, Z_2 being

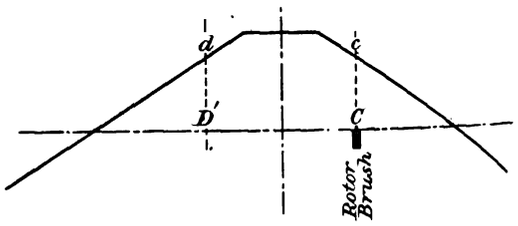

FIG. 6.

the number of conductors in the rotor winding, n being the speed of rotation in revolutions per minute, and the other symbols having the same signification as before.

Referring to Fig. 6, the flux threading the short-circuited coils may be represented by the area CcD'd.

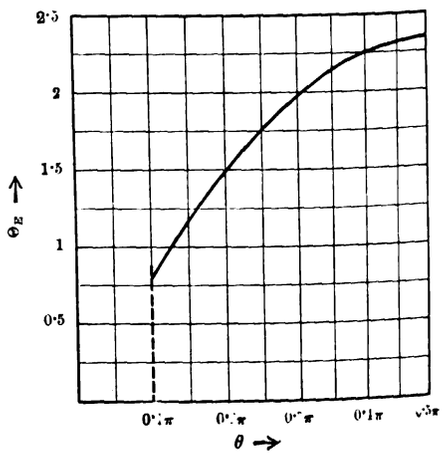

FIG. 7.

Making the necessary substitutions, we get :—

The effective value of the E.M.F. induced in the rotor winding when rotating in the field due to an alternating current in the stator winding is

$$= \frac{Z_2 n \bar{B}_{max} r l 4}{60\sqrt{2}\, p_{2r}}\left[\frac{\pi\theta-\theta^2-a^2}{\pi-2a}\right]10^{-8}. \quad . \quad . \quad . \quad .$$

Digitized by Google

For this particular case it is not important to know the value of the flux linkages represented by this expression, and we shall not, therefore, consider it further.

In the expression (3) the numerator of the quantity in brackets may be denoted by Θ_E, and Fig. 7 shows the relationship between Θ_E and θ for values of θ between a and $\pi/2$ (assuming $a = 0{\cdot}1\pi$).

It is to be noticed that the frequency of the E.M.F. induced at the rotor brushes in this way is independent of the speed and is equal to the frequency of the supply pressure at the stator terminals.

Expression (3) would appear to indicate that the E.M.F. is independent of the number of poles. This, however, is not the case, since the angles are measured in electrical (not geometrical) degrees.

If a current be caused to flow in the rotor winding the flux distribution will be as shown in Fig. 8, and we get :—

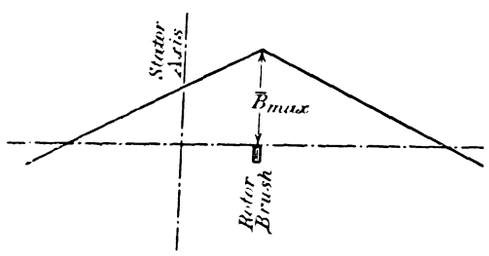

FIG. 8.

The effective E.M.F. induced at the stator terminals due to a current in the rotor winding is

$$= \frac{1}{P p_{2s}} \bar{B}_{max} l w_1 4{\cdot}44\, \nu\, 10^{-8} r^2 \left[\frac{\pi^3/3 - 2\pi a^2 - 2\pi\theta^2 + 4a^2\theta + 4/3\theta^3}{\pi} \right] \quad (4)$$

or, dividing by $4{\cdot}44\,\nu\,10^{-8}$, we get :—

The maximum flux linkages of the stator winding due to a current in the rotor winding is

$$L'_s = \frac{1}{P p_{2s}} \bar{B}_{max} l w_1 r^2 \left[\frac{\pi^3/3 - 2\pi a^2 - 2\pi\theta^2 + 4a^2\theta + 4/3\theta^3}{\pi} \right] . \quad (4a)$$

Expressions (4) and (4a) hold if θ is equal to or greater than a.

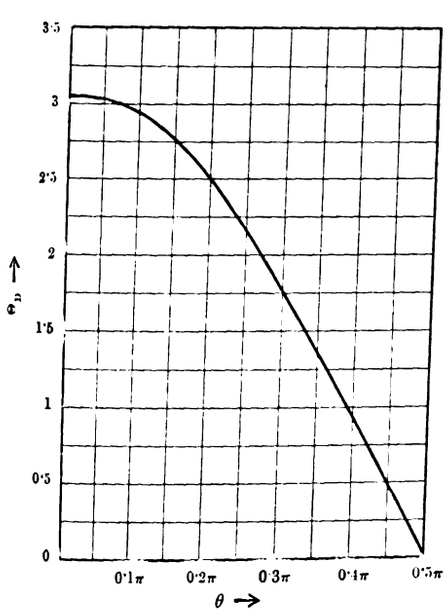

FIG. 9.

f, however, θ is less than a, a new expression must be obtained for ie flux linkages. This has been found to be

$$= \frac{\bar{B}_{max} r^2 l w_1}{P p_{2s}} \left[\frac{\pi^3/3 + \frac{4}{3}a^3 + 4a^2\theta - 2\pi a^2 - 2\pi\theta^2}{\pi} \right].$$

We shall not further consider the case of θ less than a.

In the expression (4a) the quantity in brackets may be represented Θ_D, and the values of Θ_D have been worked out for various values θ from 0 to $\pi/2$.

Fig. 9 shows a curve connecting Θ_D and θ, but this curve is, of nurse, only applicable for values of θ between a and $\pi - a$.

For the last case (case 5) to be considered we may deduce the following by considering this as a special form of case 1 :—

The effective E.M.F. induced in the rotor winding due to an alternating current in that winding is

$$= \frac{4{\cdot}44\,\nu\,\bar{B}_{max} l w_2 r^2 \pi^2 10^{-8}}{3P p_{2r}} . \quad . \quad . \quad . \quad . \quad . \quad . \quad ; \quad (5)$$

or, dividing by $4{\cdot}44\,\nu\,10^{-8}$, we get :—

The maximum flux linkages of the rotor winding due to an alternating current in that winding is

$$L''_s = \frac{1}{3P p_{2r}} \bar{B}_{max} l w_2 r^2 \pi^2 . \quad . \quad . \quad . \quad . \quad . \quad ; \quad (5a)$$

The foregoing results will now be utilised in the development of the theory of the repulsion motor.

(To be continued.)

EXPERIMENTS ON SPARK GAPS WITH ALTERNATING CURRENT.*

BY DR. W. WEICKER.

Summary.—The author examines the methods of measuring alternate-current voltages by means of spark-gaps, and shows the various influences that require to be taken into account for purposes of correction. He defines the "initial voltage" and the "limiting voltage of brush discharge," and shows how these are affected by the nature of the electrodes, by the length of the spark-gap, by moisture, atmospheric pressure, ultra-violet light and other disturbing influences.

Discharges at high voltages have been frequently studied and described, but the measurements mostly have reference to tests carried out with influence machines and induction coils over short sparking distances. Very little has been published of a precise nature, referring to sparks produced by ordinary alternating current, and the author, therefore, thinks that the following tests, carried out by him in the laboratory of the porcelain factory at Hermsdorf may be of interest. The apparatus included an alternator with an output of 10 kw., and a transformer giving 20 kw., and a voltage of 200,000, the frequency being 52. The voltage given by the transformer was always regulated by adjusting the excitation of the alternator. But spark phenomena depend not on the effective voltage, but on the maximum value, and an accurate knowledge of the wave-form was therefore necessary. This was obtained by an oscillograph of the Siemens-Blondel type, and it was discovered that the wave-form depended on the experimental arrangements, such, for instance, as the length of the conductors joined to the transformer. This made it necessary to determine the wave-form separately for each experiment. In determining the spark voltage it was found—as, indeed, Toepler had already found—that it was very important to distinguish between the different forms of discharge, and that this distinction helps to clear up many points which would otherwise seem of a puzzling nature.

If with two given electrodes the spark voltage is plotted as a function of the distance between the electrodes, it is not usual to obtain any steady curve. It is found that sparks tend to appear when one form of discharge passes into another. For purposes of definition, it is necessary to note the following: The "initial voltage" is defined as that at which the first faintly visible glow appears; the "limiting voltage of glow discharge" is that at which the glow gives place to the brush discharge; and the "limiting voltage of brush discharge" is that at which the brush passes into the arc. With ordinary alternating current it is generally sufficient to distinguish between the "initial voltage" and the "limiting voltage of brush discharge." In Fig. 1 are given curves showing results obtained with pointed and spherical electrodes; but it must be understood that the conditions under which these curves were taken were merely accidental—that is, they correspond to certain chance conditions of the atmosphere at the moment of test; and it will be shown later that the atmospheric conditions are a very important element in the calculation. On the other hand, the results shown in Fig. 2 are those corresponding to certain stated conditions—viz., a temperature of 20°C., a barometric pressure of 740 mm. of mercury, the presence of 50 per cent. of relative moisture, and an exact sine wave voltage.

With pointed electrodes it is specially important to distinguish between the different forms of discharge. If the spark-gap is very small, the "initial voltage" may be the same as the "spark voltage," but not otherwise. The shape of the extreme tip is of the greatest importance, and the slightest injury to the tip affects results enormously. A blunted tip requires a much increased voltage to jump

* Abstract of an article in the "Elektrotechnische Zeitschrift."

Digitized by Google

the gap. With increased gap, the glow discharge begins, and passes at once with an increase of voltage into a spark discharge. With very sharp and very blunt tips, the spark voltages are apt to be irregular. With a further increase of gap, the glow is succeeded by the brush and then this passes into the spark discharge. But here again the shape of the tip is very important. With very sharp tips with a taper of less than 7 deg. there is often no brush discharge with long spark-gaps, the sparks immediately succeeding the glow; with a taper up to 15 deg. a partial brush discharge may accompany the sparks; with a taper of more than 20 deg. a well-defined brush appears preceding the spark discharge which now takes place at a constant voltage over a constant gap—*i.e.* the voltage is independent of any further increase of the taper, until we come to quite blunt conical tips, with angles of more than 100 deg. If, for a constant gap, the spark voltage is plotted as a function of the taper, it is found that very high voltage values correspond to very sharp tips; but the voltage quickly falls to a constant normal value for increased tapers, until with very blunt tips it begins to rise again slightly. As may be imagined, sewing needles, which are often used for this class of work, proved almost useless on account of the sharpness of their tips. For purposes of measurement with pointed electrodes, the "limiting voltage of the brush discharge," which is almost independent of the shape of the tip, is the main feature, and involves voltages above about 60 kv. or 70 kv.; and for this it is best to use tapers of not less than 20 deg., the extreme tip being preferably filed off.

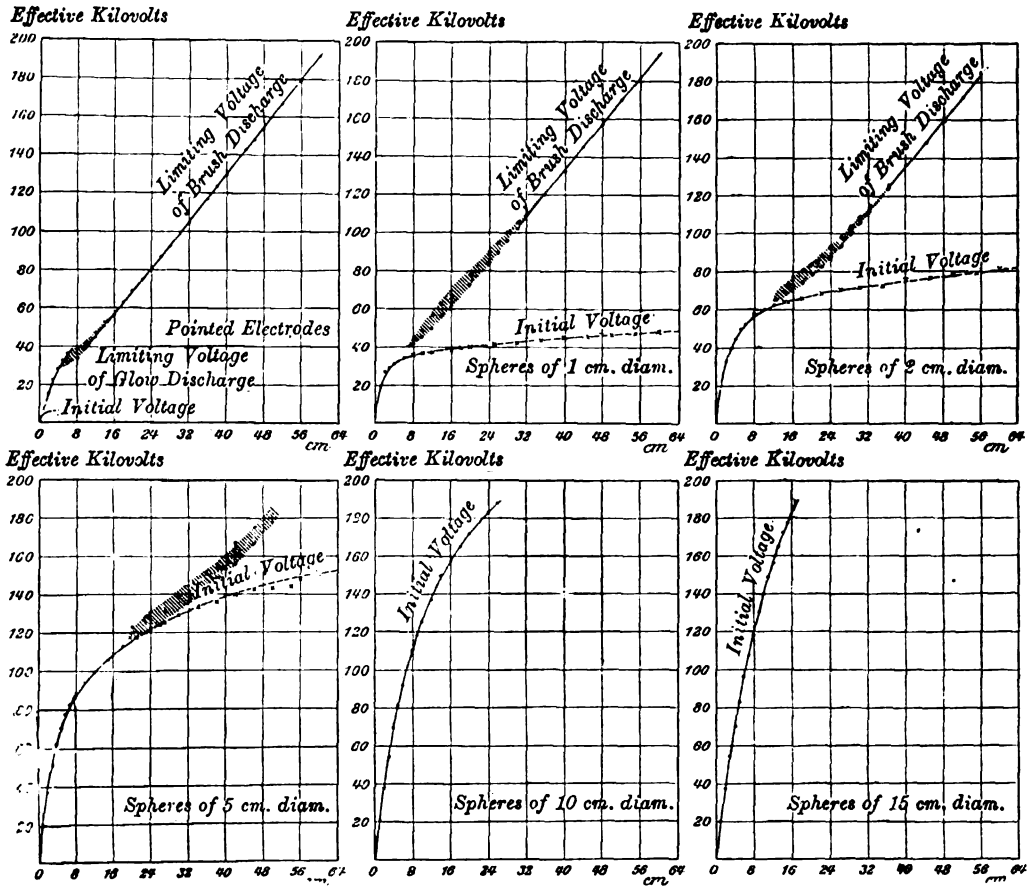

FIG. 1.—SHOWING THE RELATION BETWEEN VOLTAGE AND SPARK-GAP WITH ELECTRODES OF DIFFERENT TYPES.

The effects of the atmosphere on these phenomenon must next be examined, and here again it is necessary to distinguish carefully between the "initial voltage" at which the first faint glow is observed and the "limiting voltage of brush discharge." Considering the "initial voltage" first, the effect of moisture in the atmosphere was first examined, the barometric pressure and the temperature being kept as nearly constant as possible. An artificial state of dampness was produced by gradually passing steam into the room; but there was found to be no relation between the amount of moisture and the initial voltage. Results obtained with short spark-gaps by other observers show that the "initial voltage" is proportional to the density of the atmosphere; therefore, if the barometric pressure is constant, the "initial voltage" would be inversely proportional to the absolute temperature. This was proved to be the case by experiments on spherical electrodes ranging from 2 cm. to 10 cm. in diameter, with spark-gaps up to 50 cm. The range of temperature at Hermsdorf, where the tests were carried out in the open, is very great, and as the experiments extended over several years, temperatures reaching from 33°C. to 23°C. below zero were recorded. It has also long been known that for low voltage values there is a direct proportion between the "initial voltage" and the barometric pressure. The correction for errors of this kind is, therefore, easily made. The author examined the matter from the point of view of higher pressures. One test was with spherical electrodes of 10 cm. diameter and with a spark-gap of 10 cm., the pressure rising to 127 effective kilovolts, and another was with spheres of 2 cm. diameter and a spark-gap of 35 cm.; the results confirmed the law as stated above. It may be stated in passing that the formula, due to Toepler, connecting the sparking voltage for spherical electrodes with barometric pressure and temperature, gives results agreeing very closely with those obtained by the author. Toepler's formula was only intended to apply to pressures up to 60,000 effective volts; but it now seems to apply for much higher pressures up to 200,000 effective volts and for spark-gaps up to 60 cm.

The next point to examine is with regard to the "limiting voltage of brush discharge," and the effects produced by the atmosphere. This case is much more complicated, seeing that the amount of moisture in the air affects matters as well as the barometric pressure. Pressure, temperature and moisture are the three independent variables, and their effects have now to be considered. As has been already shown, there exists a linear relation between the length of the spark-gap and the "limiting voltage of the brush discharge." Such deviations from this law as could be detected were due to unavoidable experimental errors. For instance, on different occasions curves were constructed showing the relation between spark-gap and the limiting voltage of brush discharge; these curves were in all cases straight lines, but their inclinations to the axes of co-ordinates were different, owing to the different atmospheric conditions on the days of test. Still, these straight lines appeared to intersect at a point corresponding to a spark-gap of 6 cm. This seems to show that 6 cm. is in this particular case that gap for which temperature and moisture produce no effect; and probably it is correct to suppose that this is the smallest gap over which a brush discharge is possible. The influence of moisture and temperature is mostly seen in the retarding effect which is exerted on the growth of the brush discharge, and they do not appear to exert any influence on the discharge of sparks from the body of the electrode. In a darkened room it is clearly seen how an increase of moisture hinders the growth of the brush discharge; and if the atmosphere is saturated with moisture there is scarcely any sign of a brush discharge before the spark appears. The following equation expresses the general conditions for the brush discharge—viz.,

$$P = c_1 + (F - 6)kZ(q, t),$$

where P is the voltage, F is the length of the gap in centimetres, c_1 and k are constants, and $Z(q, t)$ is a function, at present unknown, of the absolute moisture q (expressed in grammes per cubic centimetre), and the temperature t.

The influence of moisture was next tested over a constant spark-gap between pointed electrodes and also between two small spherical electrodes. If the "limiting voltage of the brush discharge" is plotted as a function of the relative moisture, a curve is obtained which is to all intents and purposes a straight line, if the values below 40 per cent. relative moisture are neglected. The function $Z(q, t)$ between the limits of 40 and 100 per cent. relative moisture is therefore, capable of being written in the form

$$Z(q, t) = c_2 + a.\, q,$$

where c_2 is a constant depending on the temperature, q is the absolute moisture expressed in grammes per cubic centimetre, and a is the increase in the voltage for a moisture of 1 gramme per cubic centi-

Digitized by Google

metre over a spark-gap of a length of 1 cm. The spark voltage in this case, therefore, is given by the following equation—viz.,

$$P = c_1 + (F-6) \cdot (c_2 + a.\ q).$$

For an exact determination of a, tests were carried out over all sorts of lengths of spark-gaps, and the average value was found to be 0·059, or, roughly speaking, 0·06 for voltages following a sine wave and for a temperature of 20°C. For lower temperatures the value of a increases slightly, and for a temperature of 6°C. amounts to 0·07. From other readings the value of c_1 was found to be 30 kv. (effective), and with a temperature of 20 deg. the value of c_2 was found to be 2·8. The above equation can, therefore, be written in the following form

$$P = 30 + (F-6) \cdot (2{\cdot}8 + 0{\cdot}06q) \text{ effective kilovolts.}$$

The influence of the temperature on the limiting voltage of the brush discharge is very difficult to ascertain, because a change of temperature affects generally the absolute as well as the relative moisture. The best results were obtained in the open air on bright days, and experiments were made at different times of the year over constant spark-gaps and with constant barometric pressure. The result seemed to be that the spark voltage decreased rather more rapidly than it would if it followed the law of inverse proportion to the absolute temperature. The effect of barometric pressure was also deduced from a large number of experiments, and the "limiting voltage of the brush discharge" seems to increase more rapidly than the density of the atmosphere, and this increase seems to be independent of the length of the spark-gap. Roughly speaking, it may be said that an increase of 10 mm. in the height of the mercury column raises the voltage by about 2·4 per cent. Still, at a given spot, the variations of barometric pressure are not great, and it is not certain that it is possible to draw any general conclusion from results obtained n this way.

The frequency was changed from 15 to 75, but these changes appeared to be without effect on the maximum values, as opposed to the effective values of the spark voltage. The effective values did, indeed, vary somewhat, but this was due to the reaction of the magnetising current of the transformer on the field of the generator,

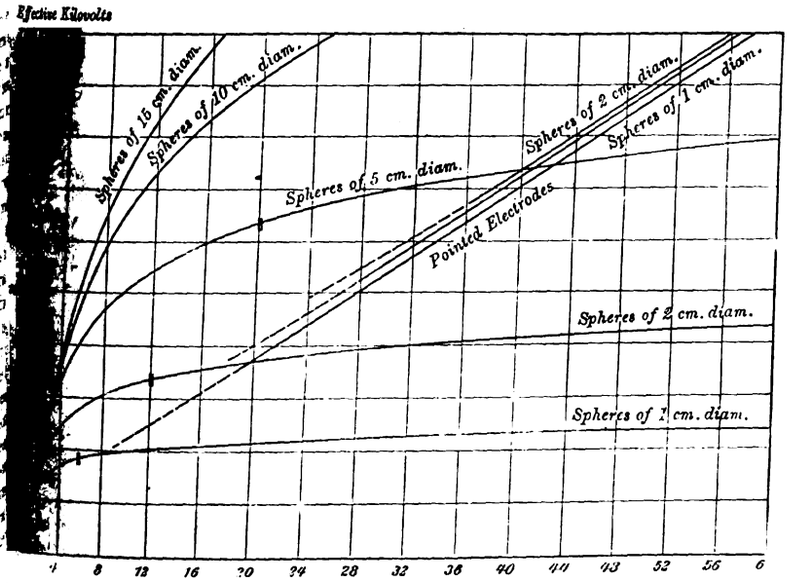

FIG. 2.—SHOWING THE "INITIAL VOLTAGE" AND THE "LIMITING VOLTAGE OF BRUSH DISCHARGE" BETWEEN SIMILAR ELECTRODES OF DIFFERENT KINDS.

These curves hold for a barometric height of 740 mm. of mercury, a temperature of 20° C., and a relative midity of 50 per cent., the voltage-waves being exactly sine-shaped. The short vertical double lines give the ite up to which the "Initial Voltage" coincides with the sparking-voltage.

whereby a considerable distortion of the wave-form was produced, esulting in a difference in the amplitude factor. The capacity of he electrodes appears also to have no effect, apart perhaps from a light displacement in what may be called the neutral territory that es between the various forms of discharge, and forms a kind of ransition area in which the one passes into the other. Various bservers have noted the effect of ultra-violet light, and the author, herefore, examined the results produced by a couple of arc lamps. t was found that the radiation from the lamp had a marked effect n the "initial voltage," which was lowered by amounts up to 4 per ent.; but no effect was produced on the "limiting voltage of brush scharge," probably because ionisation was already present as a sult of the brush discharge itself.

A source of error that is frequently fogotten lies in the effects oduced by the connecting wires or by the presence of large earthed odies. The effect is specially noticed in the "initial voltage," whereas so long as the brush discharge itself is not affected the "limiting voltage of brush discharge" appears to be unaffected. In a certain case, which may be taken as typical, the gradual shifting of the position of some connecting wires had the effect of raising the "initial voltage" from 68 kv. to 87 kv. For purposes of measurement, the "initial voltage" may be taken between two fairly large spherical electrodes, the mean of several readings being taken with a view to excluding any chance effects due to irregularity in the surface; and it is well to see that the electrical field is so arranged as to be likely to be as free as possible from reactive disturbances. These disadvantages are not so marked in the case of pointed electrodes; but, on the other hand, in this case, the more pronounced effects of temperature, pressure and moisture are counterbalancing considerations.

In conclusion, it may be pointed out that if attention is directed to the various corrections necessary for reducing the readings to a pre-arranged system of standard conditions, it is possible to obtain wonderfully consistent results.

The original article contains a number of curves and figures relating to the various tests which have had to be omitted from the present abstract owing to considerations of space.

ECONOMICAL AND RELIABLE POWER GENERATION BY OVERTYPE SUPERHEATED STEAM ENGINES.*

BY W. J. MARSHALL.

Summary.—The author considers that the type of steam plant in which the engine is mounted on the boiler can compete as regards low cost of running with the internal-combustion engine. He describes the engine manufactured by Messrs. R. Garrett & Sons, and gives results of tests on actual installations.

On account of the severe competition which they have felt from internal-combustion engines, steam engine builders are now able to produce steam plants having a fuel cost quite on a par with that of internal-combustion plants, and having other advantages which make them preferable to internal-combustion plants where reliability, flexibility and overload capacity are essestial. The author's Paper deals particularly with plants of comparatively small capacity, say, up to 500 B.H.P.

The name "overtype superheated steam engine" does not in itself sufficiently describe the plant, consisting as it does of engine, boiler, superheater, air-pump, condenser, &c.; in fact, all the integral parts which go together to make a complete steam plant. This form of plant is known by various names. In Germany the term "locomobile" has been applied to it, in France it is called "demi-fixé," and in this country it is sometimes known as the "semi-stationary engine." It is a direct development of the well-known semi-portable engine, but the element of portability which seems to be implied in the above names does not mean that it is an engine which is only to be used for temporary purposes, although the great simplicity of the foundation and the arrangements generally of the plant render it an easy matter to move the plant from one position to another should this be desirable at any time.

The overtype superheated steam engine consists of a special tubular boiler, having the superheater placed in the smoke box. The engine is mounted on the boiler, and the air-pump, feed-pump, &c., are attached to the side. The boiler forms the foundation or bed-plate for the engine. The result of this arrangement is that the steam-pipe losses are reduced to a minimum, and the full value of superheated steam can be employed. The cylinders can also be jacketed with high-pressure steam from the boiler without any loss due to drains and steam-traps, as the cylinder casing forms a portion of the steam space of the boiler.

A number of eminent firms are now manufacturing this type of steam plant, but it should be recorded here that the German firm, Messrs. R. Wolf, of Magdeburg, was the first to apply this type of engine to any great extent. Messrs. Richard Garrett & Sons, of Leiston, Suffolk, were the first English firm to take up the manufacture of this type of engine, and they also have made a considerable number of these engines and have had great success with them.

* Abstract of a Paper read before Section G of the British Association at Portsmouth.

Digitized by Google

In general principles the Garrett engine follows the lines laid down by our friends in Germany, but in details of construction the Garrett engine follows British practice, and, being more massive in construction, is more easily kept in good order and condition.

Fig. 1 gives the general appearance of the Garrett engine, and indicates clearly how the arrangement is carried out. The boiler is what is sometimes known as a "Cornish multi-tubular boiler," in that it has a single circular furnace and heating surface consisting of smoke tubes, through which the products of combustion pass. This type of boiler gives the large steam and water space of the Cornish boiler, together with the high efficiency of the locomotive-type boiler. A special feature of the boiler, and one which does away with all the disadvantages of a tubular boiler, is that the whole of the furnace and the tube system can be readily withdrawn for cleaning and inspection. The actual time taken to withdraw the tube system and replace it is from 5 to 6 hours.

The saturated steam from the boiler is conducted first to a superheater, which is situated in an extension of the smoke box. The superheater consists of a number of zig-zag coils of solid-drawn steel tubes expanded into cast-steel headers, and the steam in passing through these tubes travels in the opposite direction to the flow of the hot gases past the tubes, thus ensuring that the maximum efficiency of the superheater is obtained. The joints in the pipes connecting the superheater to the boiler and to the engine are situated outside the smoke box, where they can be readily disconnected, and the superheater itself can be completely withdrawn from the chamber in a very easy manner. A notable point of difference between English and German design in respect of the superheater is that, in the former, the coils are more accessible for cleaning, and are placed in such a position that they do not interfere with the free use of a tube brush for cleaning the boiler tubes. In the latter the coils are not so accessible, and the smoke tubes of the boiler cannot be cleaned by a steam jet, which is not sufficient to remove the deposit with many classes of fuel.

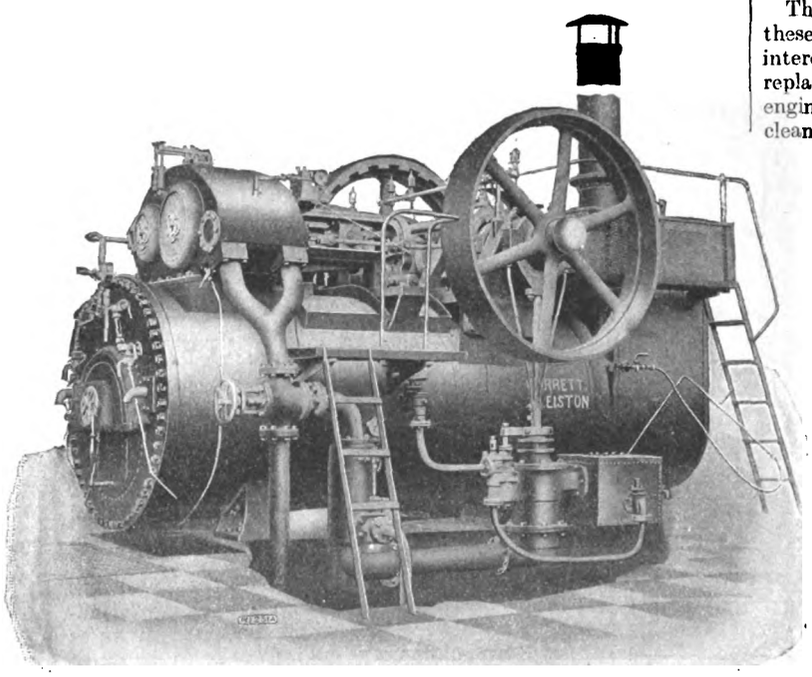

FIG. 1.—GENERAL VIEW OF A GARRETT PLANT.

From the superheater the steam is conducted to the engine, which is a side-by-side compound engine fitted with piston valves to high and low-pressure cylinders. The main crank-shaft journals are of the self-oiling type, and all other points are fitted with sight-feed lubricators. With superheated steam care must be taken that the cylinder lubrication is carried out properly, and to ensure this a positively driven sight-feed lubricator is supplied, which forces the oil both to the high and low-pressure piston valves, and thus the whole of the interior of the engine is efficiently lubricated.

The engine is governed by varying the cut-off in the high-pressure cylinder, a highly sensitive and powerful crank-shaft governor operating upon the high-pressure piston valve. This arrangement gives high economy at light loads, especially as superheated steam is used and initial condensation consequently reduced to a minimum. From the low-pressure cylinder the exhaust steam is led to a jet condenser of a simple and efficient type; where necessary a surface condenser can be employed. The condensed water and steam are drawn away by means of an air-pump driven from crank-shaft of the engine. To the air-pump crosshead is connected the feed-pump, which in Fig. 1 is shown with its suction pipe connected to the hot well, a plan that can be adapted when there is an ample supply of cooling water.

Where a cooling plant is used, it is not advisable to take the feed water from the hot well, as there is a chance of putting large quantities of oil into the boiler, but every engine is fitted with a Wilkinson patent direct-contact internal feed-water heater, so that cold feed can be used without any fear of damage to the boiler, and with the highest efficiency.

It will be seen from this brief description of the Garrett engine that the whole plant is of very straightforward design, and in no way is anything new or untried embodied in this design.

In October, 1909, Capt. H. Riall Sankey carried out a seven-hours' test on a standard Garrett engine of 50 B.H.P. rated output, and in Table I. are given some of the principal figures obtained on this test. It will be agreed that the figure of 1·21 lb. of coal per brake horse-power-hour is really astonishing for an engine of such small size.

It is not necessary to enter into a detailed examination of the reasons why such a high economy is obtained, but put briefly they are as follows: (1) The boiler, superheater, and engine are carefully designed with regard to their proportions to each other for the output required. (2) The steam pipe losses are eliminated. (3) Cylinder condensation is eliminated by the use of superheated steam and by jacketing the cylinders with live steam from the boiler without drainage losses.

The author proceeds to describe an actual installation of one of these engines in a flour mill. This particular installation is of special interest as the overtype superheated steam engine was put in to replace a suction-gas plant. It was found with the suction-gas engine that a great deal of time had to be spent overhauling and cleaning in order to obtain a continuous run, and that even with this attention it occasionally failed during the week's run. It was also found that the speed was liable to vary considerably, and, in spite of a very heavy flywheel, the drive was somewhat irregular.

None of these difficulties are experienced with the superheated steam engine, and since it has been at work it has actually been found that the cost of fuel per sack of flour made is lower than was obtained with the suction-gas engine. This is a very praiseworthy result, especially when it is taken into consideration that the steam engine is at the present time running at only about 0·65 of its full load.

In Table II. are shown actual figures recently taken from a day's run of this mill in ordinary work. These show that the high economy obtained on the test-bed is still maintained under running conditions.

Further figures are given in Table III. for the case of an engine driving a weaving factory.

One of the most important advantages of this type of engine is the readiness with which any type of fuel can be used, and the economy with the other types of fuel is proportionately as good as that obtained with steam coal. Special furnaces have to be supplied for some of these fuels. In one case an engine of this type gave 1 B.H.P.-hour with a consumption of 3·9 lb. of wood refuse, consisting of shavings, chips and saw-dust. Various types of furnaces for special use are illustrated in the Paper.

It has already been mentioned that the superheated steam engine is a successful rival of the internal-combustion engine. The internal-combustion engine has achieved its success by reason of its very low fuel consumption, this fuel consumption being so much lower than that obtained with the ordinary type of separate engine and boiler using saturated steam that manufacturers are prepared to put up with a certain amount of unreliability in order to obtain the economy. This has not always been a wise procedure, as is indicated by the number of factories which have gone back to steam engines after having adopted internal-combustion engines.

Again, the actual cost of fuel in any factory is by no means the most important of the various items which make up the cost of power production, and its relative importance varies according to the type of factory. The author gives the following hypothetical case as a conservative estimate for an average example:—

Assume that a machine shop employing 100 men—whose average wages are 7d. per hour—requires an engine of 100 H.P. to drive it. The total amount of wages per hour comes to £2·9. For management expenses, &c., the usual figure to add is 100 per cent., making the prime cost of running the shop £5·8 per hour. Taking a 54-hour week and 50 weeks per annum, and the following prices per ton of fuel: Steam coal 16s., anthracite 26s., fuel oil 45s., and including the stand-by losses per hour of the overtype superheated steam

Table I.—*Results obtained by Capt. H. Riall Sankey.*

Duration of trial	7 hours
Revolutions per minute	201·5
Mean temp. of superheated steam	536·5°F.
Average indicated horse-power	58·25 H.P.
Average brake horse-power	55·6 H.P.
Mechanical efficiency	95·5 per cent.
Water evaporated per pound of coal	8·91 lb.
Coal per brake horse-power-hour	1·21 lb.
Water per brake horse-power-hour	10·66 lb.
Calorific value of coal	14,260 B.Th.U. per lb.

Table II.—*Test in a Flour Mill.*

Duration of trial	12 hours
Coal per hour	164·5 lb.
Temperature of steam	540 to 550°F.
Vacuum	24 in. to 24½ in.
Speed	170 revs. per min.
Calorific value of coal	12,404 B.Th.U. per lb.
Moisture in coal	10·29 per cent.
Mean indicated horse-power	115·8 H.P.
Mean B.H.P. at 92 per cent. efficiency	106·5 H.P.
Coal per indicated horse-power-hour	1·42 lb.
Coal per brake horse-power-hour	1·55 lb.
Corresponding consumption per B.H.P.-hour of dry coal of 14,000 B.Th.U.s per lb. value	1·24

Table III.—*Week's Test in a Weaving Factory.*

Duration of test	Running time	49 hours
	Standing time	119 hours
Coal used while running*		3,420 lb.
Coal used while standing		1,175 lb.
Power developed, calculated from the number of machines in use		45 to 50 B.H.P.
Coal per brake horse-power-hour running		1·55 lb. to 1·4 lb.
Coal per hour standing		10 lb.
Calorific value of coal		About 13,500 B.Th.U. per pound

engine plant at 10 per cent. of the total coal burnt per hour at full load, and those of the suction-gas plant at 5 per cent. of the same quantity, the Diesel engine having no stand-by losses whatever, the following is the cost of fuel for each type of engine :—

——	Steam.	Suction-gas.	Diesel.
Consumption per B.H.P.-hour ... lbs.	1·5	1	0·5
Consumption per week ..... lbs.	8,100	5,400	2,700
Stand-by consumption per week lbs.	1,710	570	nil
Total consumption per week ... lbs.	9,810	5,970	2,700
Cost per week	£3·5	£3·46	£2·7
Cost per annum	£175	£173	£135

This comparative statement shows that under the above conditions the plant having the lowest fuel cost is the Diesel engine, which shows a saving of £40 per annum over the superheated steam engine, but it should also be noted that if—through bad starts or involuntary stops—the power supply be interrupted to the extent of 10 hours per annum, the prime cost of such stoppages would amount to £58, absolutely wiping out any gain due to lower fuel consumption.

If we carried this comparison still further, it would be found that the capital cost of the Diesel engine would be considerably higher than that of the superheated steam engine, and, consequently, the capital charges per annum would be greater. These form a very considerable item in the cost of power. Further, the steam engine can be run satisfactorily by a man of a lower order of skill than that required by Diesel or suction-gas engines, and his wages would consequently be less.

In addition, the wages required for maintenance would be less, as the parts requiring attention about a steam engine can be attended to by an ordinary driver, whereas with the internal-combustion engines expert mechanics are necessary to effect adjustments and repairs. In the above comparison the load has been taken at an average of 100 B.H.P. This average might be that of a very fluctuating load, which might range between 60 and 150 B.H.P.

The greater the difference between the peaks and hollows of the load curve the more striking is the advantage of the steam engine, on account of the fact that the internal-combustion engine has a very definite limit as to the maximum load which it is capable of dealing with, and, consequently, engines sufficiently large to deal with the peak loads must be installed, increasing the capital cost and, in the case of the suction-gas engine, giving very poor results as regards economy on the lighter loads.

On the other hand, the steam engine is capable of producing, when required, as much as 50 per cent. above its normal load for considerable periods, and, owing to its high mechanical efficiency, maintains a low consumption per brake horse-power over a wide range of loads. Fig. 2 illustrates this feature of the superheated steam engine in comparison with the suction-gas engine very clearly.

From these curves it is clearly shown that the cost of fuel per brake horse-power per hour with the superheated steam engine is very nearly constant over a wide range of loads, and does not increase on light loads to anything like the same extent as with the suction-gas engine. A further advantage of the steam engine is that the exhaust can very readily be used for heating purposes when required. In the weaving factory previously referred to, the exhaust steam, on its way to the condenser, is conducted round 600 ft. of the heating pipe during the winter months, and is sufficient to keep a room 300 ft. long by 75 ft. wide at the proper temperature. This heat is obtained at no cost.

The author feels that he has merely touched on the fringe of a very large subject, but is confident that the few facts he has brought forward show that, as a prime mover, the steam engine is still more than able to hold its own. Every case must be considered on its merits, and there are admittedly propositions which are very admirably filled by internal-combustion engines. He is, however, of opinion

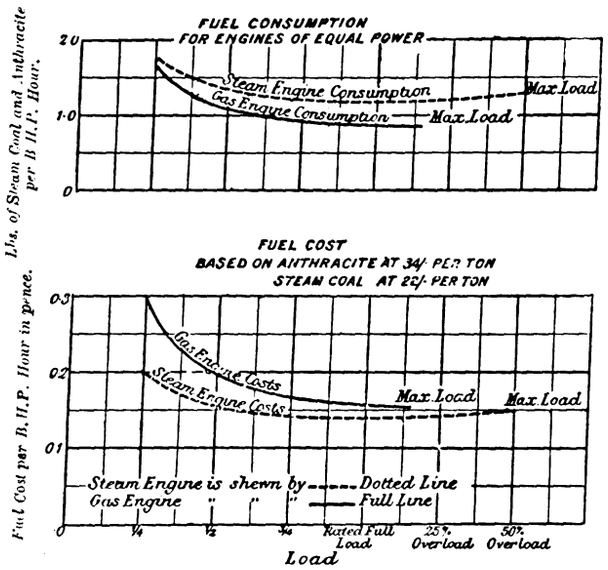

FIG. 2.—DIAGRAM OF COMPARATIVE FUEL CONSUMPTION AND FUEL COST OF SUPERHEATED STEAM ENGINES AND SUCTION GAS ENGINES.

that the use of the internal-combustion engine has latterly become somewhat of a fashion, and is certain that when the overtype superheated steam engine is more widely known it will take the place of the internal-combustion engine in a great number of power propositions.

THE FONTANA MAST.

The following particulars, which have been supplied by the inventor, Herr A. Siewert, and the manufacturers, of an extensible metallic mast that is being tried in Germany and possesses some novel features, should prove of interest. The apparatus is called the Fontana mast, and it was designed to provide a metallic mast which can be quickly raised or lowered, but without the disadvantages of a telescopic mast. This latter has not come into very extensive use for several reasons, the main one being that since the tubes must fit into each other very closely, their erection is likely to be hampered by sand or ice, or in other cases by the rusting of the metal. In addition, where a telescopic mast has to carry a load it is difficult in practice to erect it without using complicated mechanical apparatus at the base of the mast; this makes it expensive and limits its applications.

The Fontana mast is of interest owing to the new principle involved, and it is claimed that the design overcomes most of the drawbacks which up to the present time have limited the applications of such masts in electric work. Its construction is most simple, as will be noticed from the illustrations herewith. Considering, for the moment, a four-sided hollow mast, this is formed of four flexible steel strips (*see* Fig. 1). The edges of these strips have teeth cut in them in such a way that the teeth of one strip interlock with the recesses of the adjoining one, so as to join the four strips at their edges. The teeth project to some extent. This makes up a hollow column, and

* For 10-12 hours the engine was run non-condensing, thus affecting the result of the test.

Digitized by Google

it remains to brace it. For this purpose thin sheet steel brace plates are placed at frequent intervals.

The mechanism for raising or expanding a mast of this kind is seen in Fig. 2, illustrating a four-sided section. The steel strips are wound upon the drums AA, and on two corresponding drums placed in the front and rear. A second set of drums B is mounted below to feed

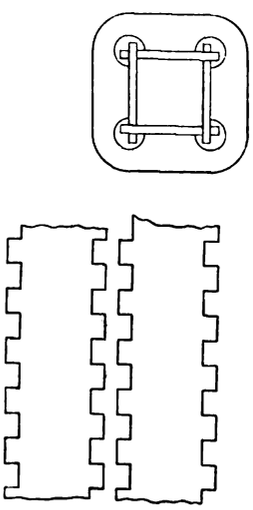

Fig. 1.—Toothed Strip and Brace Plates.

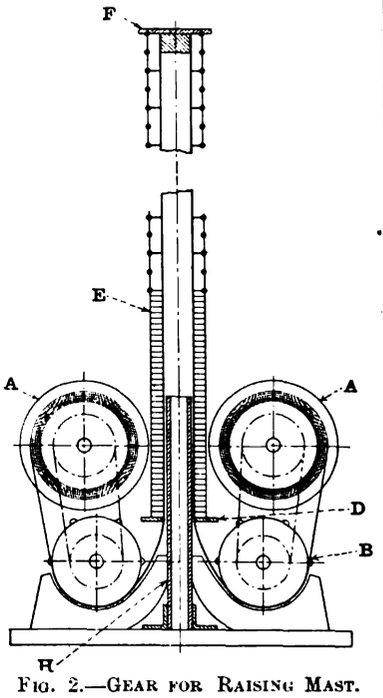

Fig. 2.—Gear for Raising Mast.

out the strip and guide it properly. These latter drums have projecting teeth around the centre which engage in holes in the steel band. A chain drive connects both drums, and the lower or feeding rollers are driven by a hand crank or in other cases by an electric motor.

As the four steel bands pass up through the guide plate D they become interlocked and form the steel tube. Upon the guide plate

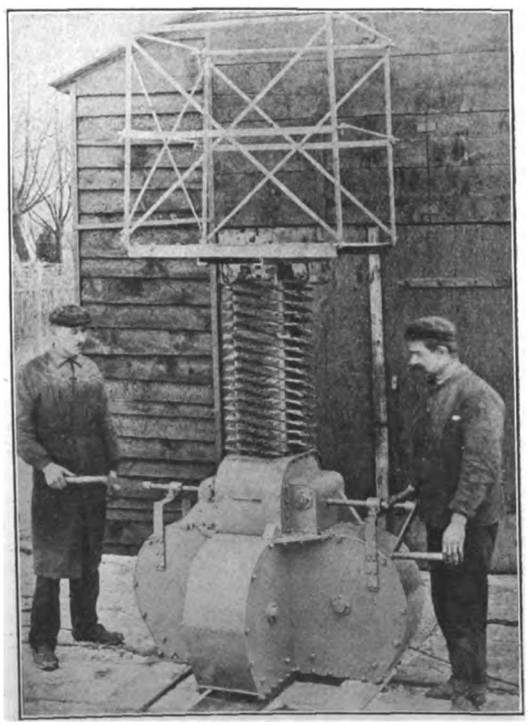

Fig. 3.—View of Mast when Nearly Lowered.

is a pile of section discs E. The top head of the mast F carries the first of a set of links which go to join all the section plates. When the head F rises in the first place, it picks up the first section disc by means of the first four links placed on the four sides, so that the disc is automatically fitted around the column. As the mast continues to rise, the second disc is taken along in the same way; the result is that the section discs are situated all along the mast, their spacing depending on the length of the link which is determined according to circumstances. A light portable mast, such as is used for wireless telegraphy, can be raised to 20 metres height using a base about 1 metre square. When lowered, the height of the apparatus is only 1·7 metres and it weighs 175 kgm. The bending stresses are taken up by a short column, H, which projects up the centre and transmits the stresses to the base. Means are provided for clamping the base of the mast tightly against the bottom column.

A crank attached directly to one of the drums B, or by gearing, can be used for raising and lowering the mast (Fig. 3) and the remainder of the drums do not need gear drive, as the rest of the strips are drawn along by means of the interlocking teeth. It is evident that sections varying from three sides to eight sides can be employed, but in practice the square or hexagonal forms are found to be best; the eight-sided form is more complicated and not much more useful. The mast is strongly braced by the section discs; these are calculated so that the mast can stand a given maximum load without the steel strips bending. The length of the teeth which engage with one another must be such that the strips are prevented from bending inwards. For stamping the strips and obtaining the spacing of

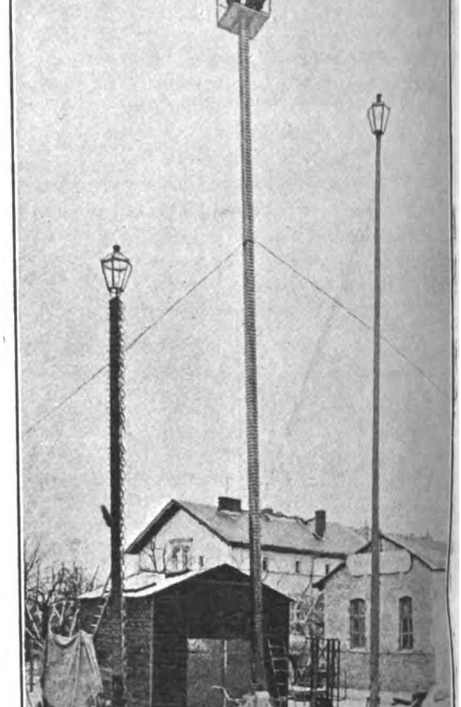

Fig. 4.—View of Mast in Use.

the discs a set of curves are used, based on a load of 2,500 kg. per square cm., assuming a certain thickness of strip and a certain factor of safety.

The strips employed are made of tempered crucible steel or of Swedish steel of great tensile strength. For the lighter masts the thickness of metal should be at least 1·5 mm., and for heavier masts this is increased to suit the case. The Fontana masts, of which one is shown erected in Fig. 4, are made in sizes to reach a height of 80 ft. and can carry a load of 2 tons. The manufacturers are the Fontana Maste und Träger Gesellschaft, Bernburgerstrasse 24-25, Berlin.

Electricity in Textile Mills.—The "Electrical World" in commenting on the recent appointment of a Committee in this country to investigate the application of electricity in textile mills, says: "Apparently knowledge of the great progress in this country in the utilisation of the electric drive in such mills, which dates from about 1894, has not penetrated to the British Isles."

THE POSSIBILITY OF ESTABLISHING A NEW STANDARD OF SMOKE EMISSION FOR FACTORY CHIMNEYS.*

BY DR. J. S. OWENS.

I do not think that anyone will contradict me when I say that the emission of dense smoke from furnaces consuming bituminous coal is unnecessary and indicative of waste of fuel and bad furnace construction or working. At the same time, it should be remembered that the total absence of all smoke is in practice usually impossible of attainment when the economy of manufacturing processes requires the burning of bituminous coal. An illustration of the difficulty of avoiding all smoke is provided by the large electric generating stations, where unforeseen variations of load occur, such as the increase due to a London fog, with its accompanying demand for artificial light. Even in steady working it is practically impossible to avoid all smoke; a faint brown smoke is regarded as indicating more efficient working of boiler furnaces than none at all.

The present position therefore is this: we know that dense smoke is unnecessary, and that entire absence of smoke is impossible of attainment, but we have not yet settled what, being fair and reasonable, should be permissible in the way of smoke, having regard to the improved methods of combustion which are now at the disposal of manufacturers. This is the question an answer to which is, I submit, within our reach and should be sought for.

The Public Health Act of 1875 supplies the present standard by which smoke is judged throughout the country, except in the case of a few important cities possessing special powers on the subject. In this Act it is stated that "Any chimney not being the chimney of a private dwelling-house sending forth black smoke in such quantity as to be a nuisance shall be deemed to be a nuisance liable to be dealt with summarily under the Act."

The standard "black smoke in such quantity as to be a nuisance" takes cognisance of two separate things in relation to smoke: its quality—that is, it must be black; and its amount—that is, enough to cause a nuisance; but, while these two essentials are taken into account, it is done in such a way that it would be practically impossible to prove in any particular case either that the smoke was black or that it was in sufficient quantities to be a nuisance. The point I wish to make is that the two essentials, kind and quantity, form part of the standard.

What is wanted is a standard of efficiency of combustion from the smoke prevention point of view. This must clearly take into account the amount of fuel burnt, and—if we could measure it—the proportion of the fuel passing out of the chimney as soot would be the ideal standard. I suggest that the word "black" in the present standard should be altered to "smoke of a density exceeding" some fixed standard. The standard should, however, also include a time of emission, and the form suggested is "smoke which exceeds a certain density (as measured in a way to be determined), and which is emitted for a period exceeding so many minutes per hour."

As to how the smoke is to be measured, we may set ourselves to measure any one of the following: (1) Total quantity of soot emitted in a given time; (2) weight of soot emitted as percentage of fuel burnt; (3) density of smoke or weight of soot per unit volume of flue gases; (4) ratio of density to a standard; (5) colour; (6) opacity, or degree of blackness. In addition to deciding which of these objects to aim at, we must keep in view that whatever method is used must give reasonable accuracy and a fair basis of comparison between chimney and chimney, or with a standard; it must also be easily applied from outside the factory by a single observer.

Of these methods (1) measures the amount of pollution by a particular chimney, but takes no account of the amount of fuel burnt; and it would be unfair to limit a large fuel consumer to the same total quantity of soot as a small one. (2) is open to the same objections as (1), but it implies at least the measurement of density of smoke, volume of flue gases, and weight of fuel. It would be a fair basis for a standard, but is quite impracticable as a method for the use of sanitary inspectors.

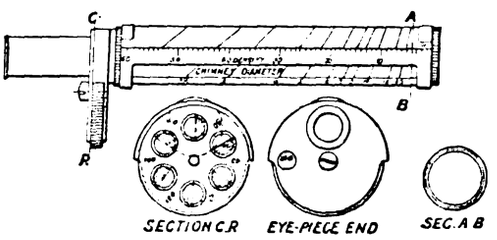
A quantitative measure of the density of the smoke might be obtained by the filtration method, in which the soot from a known volume of smoke is trapped and weighed, but it would be too cumbrous for general use. Density can also be measured optically, in which case access to the chimney or factory would be unnecessary. It would give a fair measure of efficiency of the plant, and a good basis of comparison whatever the quantity of fuel burnt or diameter of the chimney.

The measurement of the colour of smoke may be dismissed as useless, since colour bears no relation to quantity of soot emitted or evil done by the smoke.

To measure the opacity of a smoke column or its degree of blackness, which is the commonly-accepted method now adopted, is worse than useless, since it is misleading, because opacity alone, unless adjusted for thickness of column, is neither a measure of the density of smoke nor of the amount of pollution of the air.

We are thus reduced to a measurement of smoke density as the only satisfactory basis to work on. Suppose we can measure the weight of soot in a column of smoke 1 sq. ft. in section, and the same length as the diameter of the chimney. Let S = weight of soot in such a column, V = velocity of flue gases in feet per second, D = diameter of chimney in feet; the weight of soot in 1 cubic ft. of smoke will be = S/D, and the weight emitted per second $\pi D^2VS/4D = \pi DVS/4$, or $DVS \times a$ constant; that is, it varies as the volume of flue gases × the weight of soot per cubic foot. The amount of soot emitted will therefore vary directly as the volume of flue gases, assuming the density to remain constant. Or if we measure only S, the amount of soot emitted will vary as S × VD. If we assume V to be a constant value, the weight of soot emitted will vary as S × D, and the density of the smoke as S ÷ D. This shows that the measurement of S alone is of little use unless an adjustment is made for D, and it must be noted that all smoke charts now in use measure something which depends on S alone, but neglect D. It also points to the conclusion that with an adjustment for D, the measurement of S can be made to give a fair approximation to the relative weight of soot emitted or to the density of the smoke.

We can measure S indirectly on the basis of the light obstructed. For example, we may compare the degree of opacity of the smoke with a smoked glass which obstructs as much light as a smoke column of known density and thickness. Suppose, then, we take such a glass of an opacity equal to that of a column of smoke of unit thickness and standard density, we might prepare an instrument having several shades of such glass, the lightest being the standard for the smallest chimney, followed by other shades made by superimposing various thicknesses of shade 1, corresponding to various thicknesses of smoke



column or chimney diameter. We could then, by comparing the smoke at the top of a chimney with such a set, say whether or to what extent the standard was being exceeded.

The accompanying drawing illustrates an instrument which I have designed to meet the requirements laid down in this Paper. This is in the form of a small telescope, having fixed in the optical system, at a point which may be brought into the focus of both object-glass and eye-piece, a revolving eccentric disc containing a number of graduated smoked glasses arranged in cells round the centre. The glasses only fill half of each cell so that by revolving the disc, as each cell with its glass is brought successively into the axis of the telescope, the smoke may be viewed through the open half of the cell and matched to the glass in the other half. The glasses are numbered in the ratio of their thickness, and a table is provided giving the number of the glass divided by the diameter of the chimney, and thus a figure which is a measure of the density of the smoke and can be made to read the actual weight per cubic foot of soot in the smoke if desired. This necessitates the inspector knowing the chimney diameters in his district; but these may be tabulated once for all. I have found when, in instruments for smoke measurement, the smoke is viewed through a small aperture, as is essential in order not to take in too much background, that it is impossible to get true results owing to the eye being unable to focus at the same time the object aperture and the object; so that the edges of the aperture are hazy and ill-defined. This results in the whole aperture, when small, being overlaid by a hazy film, due to its ill-defined edges, which film prevents accurate readings of the smoke shade. The same applies to the aperture containing smoked glasses for comparison.

There are many difficulties remaining which apply to all optical methods of measuring smoke, but before enumerating these it is well to remind you that we have no other means of attaining our object, since all methods requiring access to a factory or a chimney are useless from the sanitary inspector's point of view. (It is easy to imagine the welcome such an inspector would get on presenting himself at the door of a factory and announcing that he had come to measure the density of the smoke from the chimney.)

*Abstract of a Paper read before Section G of the British Association Portsmouth.

Digitized by Google

As to these difficulties, it is well to consider what are the factors which influence the apparent density of smoke, as given by an observation based upon its degree of blackness; these are: (1) The true density of the smoke; (2) diameter of chimney; (3) background of smoke and shade it is compared with; (4) the colour of the smoke particles; (5) the size of the smoke particles; (6) the amount and colour of the light falling on the smoke from the observer's side; (7) the direction of the line of vision; (8) presence or absence of wind; (9) the observer's personal factor.

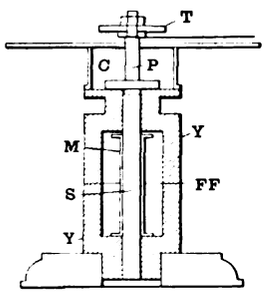
There is not time to discuss each of these in detail, but I may say that (1), (2) and (3) can be dealt with satisfactorily, (4) and (5) are probably sufficiently constant not to affect results seriously, excluding exceptional cases, (6) is the most difficult to deal with, and should be allowed for in making observations, (7) can be overcome, to a great extent, by keeping the angle which the line of vision makes with the horizon fairly constant, (8) would not, as a rule, be a serious obstacle, while (9) is not, I think, of great importance.

Assuming, then, that we have decided on the method of measurement to be adopted, and on the type of standard to be fixed, the question remains, how is the standard to be arrived at? It would seem that this might be done best by the appointment of a technical committee, which would make observations over a certain period, say, a year, of certain selected representative chimneys, where up-to-date and well-designed furnaces are installed, and bituminous coal is burnt. A consideration of the results of such observations, both as to smoke density and time of emission, should enable the committee to fix a fair and reasonable standard, both as to the density of the smoke, and the time during which such density should be permitted.

A FRICTION PERMEAMETER.*

BY W. H. F. MURDOCH, B.SC.

In making measurements with friction permeameters of the types described in a previous paper ("Magnetic Testing of Iron," "Journal" Inst. Elec. Engs., Vol. XL., p. 137) the specimen was allowed to slide a short distance on a yoke or yokes of iron, and the



SECTION SHOWING NEW TYPE OF INSTRUMENT.
(The spring is omitted for clearness.)

friction pull measured. A screw starting device was used to obtain a uniform starting impulse, and the specimen had to be reset at each reading. The heavy yoke made the instrument cumbersome, and the spring when the instrument was used as a direct reading one was attached to the sliding specimen. In addition the ends of the specimen had to be faced, which, of course, was a more or less troublesome matter. The results obtained with this type of instrument although satisfactory for moderate inductions were not so good at high inductions owing to leakage.

The accompanying illustration shows the arrangement now adopted; S is the specimen to be tested, Y the yoke faced at FF, a magnetising coil, M, is placed on the specimen, a dial, D, is attached to R, the top portion of the yoke, together with a spring, C, and a torsion head, T, attached by a collar to the pillar P.

The method of testing is first to adjust the pointer so that when the top portion of the yoke is sliding slowly, under mechanical friction only, the pointer remains at the zero of dial. The specimen is then magnetised and the angle of torsion, when steadily sliding, measured. The square root of this angle is proportional to the induction in the specimen.

It will be seen that in this instrument the same sliding surface is used for all specimens tested, the top portion of the yoke being rotated round the specimen as axis and sliding on the lower portion. The magnetic induction is kept constant during the test and the magnetic circuit remains unbroken, whilst the magnetisation is not reversed. The sliding being a continuous process, a series of readings may be rapidly taken. The specimen being cylindrical enables it to be accurately turned, and the magnetising coil acts symmetrically upon it.

In designing instruments of this tpye the areas of contact between specimen and yoke, and between the sliding surface of the yoke must be large compared with the area of the specimen itself, in order to eliminate errors in H, and the longer the specimen the less will be the effect of gap resistance. Care must also be taken that the stream lines of magnetic induction over the yoke gap are uniformly distributed, otherwise the Law of Traction will not be obeyed.

Friction on the specimen is practically eliminated first by lubrication, and secondly by making the radius of the specimen small, so that the torque due to any stray friction is small compared with the torque on the yoke sliding surface.

As regards the coefficient of friction on the sliding gap surface, since the pressure on this surface is always small the coefficient is kept invariable. Lubrication on this surface must be avoided, and the surface should be cleaned before making a test.

By using a torsion spring arrangement such an instrument may be made direct reading, and in calibrating it with a fluxmeter or ballistic galvanometer, only one point need be determined, so this operation takes but a few minutes. In testing iron the method adopted by the author is to use equal currents for the magnetising solenoid and to observe the angles of torsion for the standard piece and the specimen under test. If the instrument has been calibrated as mentioned above, a standard bar is unnecessary.

There is, however, a difficulty. The readings of the instrument are made while the pointer and dial are in motion, and it might be suggested that here an acceleration error comes in, one person moving the top of the yoke at a different rate from another. Since, however, when a reading is being taken the observer will naturally make the sliding motion as slow as possible, the acceleration error is in consequence practically negligible. For making comparisons the instrument need not be calibrated, and one observer is just as good as another so far as this error is concerned. In the same way different observers may press differently on the torsion head and the same remarks apply in this case also.

The theory of the instrument is briefly as follows:—The work done in turning the top of the yoke through a small angular distance is equal to the frictional force on the sliding gap acting through this distance. This frictional force is due to the mechanical weight acting on the gap together with a magnetic pull. If the mechanical portion of the friction is eliminated by adjusting the pointer to read zero when the specimen is not magnetised then we have only to consider the magnetic pull. When a spring is used the torque is proportional to the angle of torsion, and the frictional torque can be found by simple integration. Hence by equating these quantities we obtain a formula involving the gap induction. Since the same total number of lines pass through the gap, and through the specimen (the magnetic leakage being very small) the magnetic induction B in the specimen might be written:

$$B = k\sqrt{\delta},$$

where k is a constant, and δ is the angle of torsion.

By altering the springs the instrument may be made of considerable range, and the induction in the specimen may be pushed to a high degree without the proportionality of the readings to the true magnetic induction breaking down.

One is frequently asked what is the degree of accuracy obtainable with such instruments. Now, as is obvious, the errors are errors in H, and errors in B. Those in H depend solely on the magnetic circuit equation and may made as small as we please for any given case. The errors in B will depend on the accuracy of the reading of δ. The former errors diminish rapidly as saturation is approached, whereas since the friction pull at saturation is only slowly increasing the error at that point begins to increase.

The following figures are actual results:—

Current.	Fluxmeter reading $\sqrt{\text{Angle.}}$	Remarks.
0·25	1·892	300 turns on bobbin.
0·50	1·835	Length of specimen
0·75	1·915	2 in. Specimen of
1·00	1·909	mild steel.
2·00	1·901	
2·50	1·875	

It is therefore difficult to say what the error is in using an instrument of this type, but with properly adjusted springs measurements to within one to two per cent. seem possible at ordinary inductions.

The rapidity with which comparisons can be made seems to render the instrument suitable for practical workshop tests, more especially as practically no previous experience is necessary.

AN IMPROVED WIRELESS TELEPHONE TRANSMITTER.

BY W. DUBILIER.

Summary.—An account is given of a telephone transmitter in which two diaphragms are used, opposed to one another, and water cooling is adopted. The holder for the carbon granules is in the form of an annular space. It is found that much heavier currents can be used than with the usual type of transmitter.

In wireless telephony quite a lot of trouble has been experienced in attempting to get a transmitter that would withstand the current, ranging from 1 to 6 amperes, and at the same time respond to the variations of speech. In order to overcome this difficulty several attempts have been made to obtain a stronger effect by a number of loose contacts, or several diaphragms, actuated by the same mouthpiece. In all these cases, however, it was found that when the energy is increased, distinctness is sacrificed; that is to say, when we increase the number of diaphragms we decrease the clearness of articulation.

In some cases an attempt was made to remove the resulting heat by surrounding the carbon cup with a water jacket and circulating a stream of water constantly through it. This method was only partially successful, due to the fact that the

FIG. 1.

real point where heat is produced—the point where the carbon button makes contact with the granules—received no cooling effect at all, the jacket only serving to dissipate the exterior heat. Even though the ordinary transmitter could be used, the writers doubt its perfect working owing to its lack of amplitude in vibration. Therefore the ideal transmitter must carry the current without detrimental heating and must respond with a good vibratory effect to the spoken words.

Experiments were made with several different types of transmitters to determine how the results varied with the vibratory effect impressed upon the diaphragm. The first test was made on an ordinary Western Electric transmitter. A simple oscillograph was employed to observe the variations, It was impossible, however, to make a permanent record of the variations owing to the type of oscillograph employed, but Figs. 1 and 2 illustrate the variations and the comparative difference in the transmitters. One voltage was used for all the tests. In order to maintain the same intensity of sound, a phonograph was employed for talking, the record being run over the same portion for each test. A standard Western Electric transmitter was first employed and its change in the current flow, when spoken into, is illustrated in Fig. 1.

The next test was made with a transmitter of the double diaphragm type. This transmitter is a compromise between

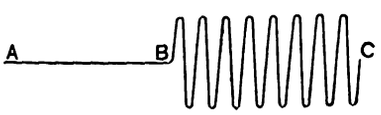

FIG. 2.

the solid-back and series arrangement. In the solid-back type the contacts are usually placed behind the diaphragm, and consequently only the increasing and decreasing of pressure on the front of the diaphragm is utilised.

In the solid back a certain amount of energy is lost, due to the vibrations of the diaphragm and back in synchronism; that is, they both vibrate to and fro in the same direction at the same time. This type, however, when properly constructed overcomes this effect to a certain extent and in actual tests a greater current could be passed through it and a larger variation was caused in the current, as shown in Fig. 2. In action the voice tones divide and act on each diaphragm, thus causing the diaphragms to act simultaneously against and away from each other.

The third test was made with a Western Electric transmitter mounted so that its diaphragm was controlled magnetically instead of by the voice tones direct. The magnets were approximately 5 in. long by 2 in. in width from pole to pole, made of the highest grade hard steel. Additional steel plates were screwed to the magnet poles and bent until they were approximately $\frac{1}{2}$ in. apart. Two-ohm windings were placed on and connected to a local transmitter and battery. The diaphragm of the Western Electric transmitter was now placed so that it held nearly the same relation to the magnet poles that a diaphragm does to the ordinary receiver. A circuit was made from the Western Electric transmitter to the oscillograph and from local transmitters around the two-ohm windings over the magnet poles. When the local transmitter was spoken into and the oscillograph action noted, it was found that the variation was greater than when the same transmitter was acted

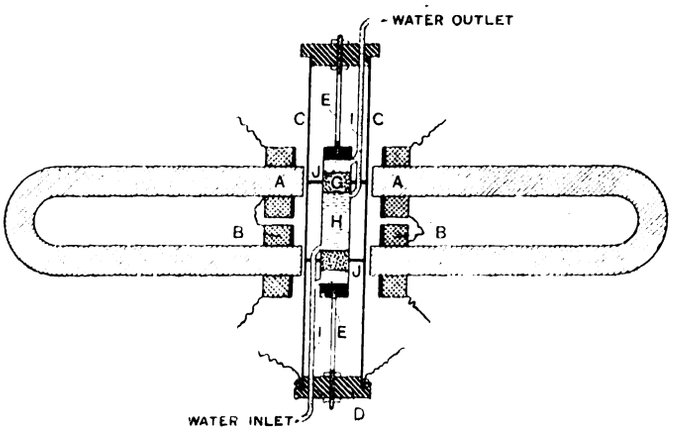

FIG. 3.—SECTION OF TRANSMITTER.

upon direct by the voice but hardly so great as when the double-diaphragm type was used. Therefore it was obvious that if we could apply the magnetic control to the double-diaphragm type the results would be still better.

This was accomplished by building up a transmitter according to the plan shown in Fig. 3. Fig. 4 shows a general view of this instrument. The transmitter complete consists of the magnets A, A, wound with the two-ohm windings B, B, and placed opposite to each other with the diaphragms and carbon containing cup between. The diaphragms are approximately 5 in. in diameter and $\frac{1}{25}$ in. thick. The ebonite disc D is used to mount the diaphragms on and is drilled with large-sized holes so as to prevent "air packing" or talking against one another.

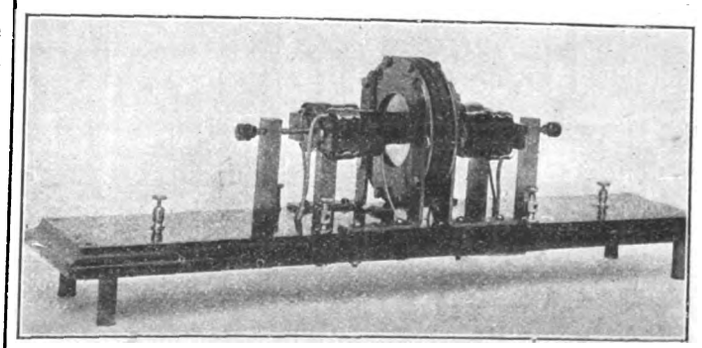

FIG. 4.—GENERAL VIEW OF TRANSMITTER.

A cross-section view of the carbon-containing cup is shown in Fig. 5. It resembles three brass rings placed within one another, forming three independent containing portions. Water circulates through the chambers F and H by means of the inlet and outlet tubes I, and the middle chamber G (Fig. 4) is used to retain the carbon granules. To make contact with the granular mass circular rings of platinum, J, J, are used, which are first soldered to the diaphragms C, C. The platinum rings are drilled with small holes round the entire circumference so as to allow a free circulation of air, and through one of these

Digitized by Google

holes the small inlet and outlet tubes are run. The contact is made in the centre of the granular mass. A mica disc is used to retain the granules in the chamber.

It would appear that this method of mounting the contact would decrease the efficiency, but experiments were first made with an ordinary solid-back transmitter made up in this manner, without the water-cooling arrangement, and the results were even better than with the usual transmitter. The advantages of this method of construction is that the contact is made round the interior of the chamber instead of being centred at one point, thus giving more room for the dissipation of heat, and the closed centre prevents packing of the granules. It also allows of cooling means which are impossible with the usual construction method. Pieces, E, E are used to hold the cup in position.

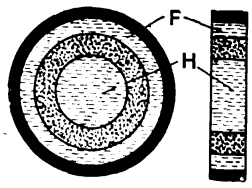

FIG. 5.—CROSS-SECTION OF CARBON-CONTAINING CUP.

A local transmitter is connected in series with a set of dry cells and the windings B. Leads are taken from the diaphragms to the aerial circuit. When the transmitter is spoken into, the current flowing round the windings varies the magnetic pull of the magnets in the usual manner, and the diaphragms, C, C, are set in vibration to the same proportion. The maximum vibration should be figured as the resultant of the two; that is, for the sake of illustration, consider that the maximum vibration of each diaphragm is $\frac{1}{16}$ in., the result would be equivalent to $\frac{1}{8}$ in.; for each diaphragm works oppositely in the same proportion.

The main feature against using this type of transmitter is the difficulty of constructing and adjusting. However, in actual practice it gives the desired results and comes near to being the ideal transmitter for heavy currents.

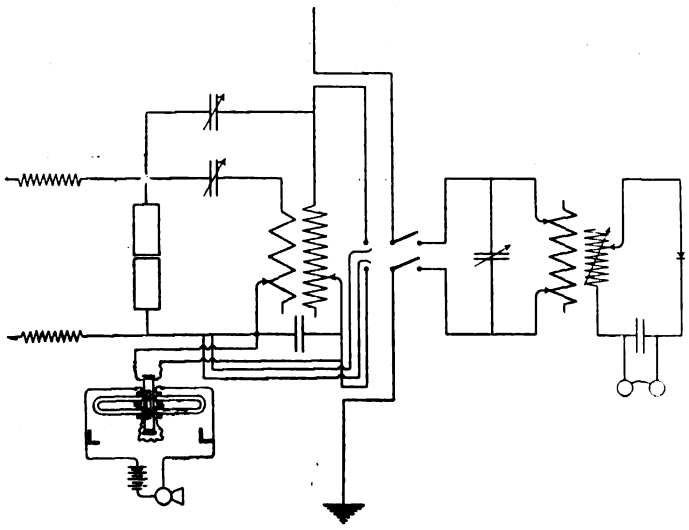

FIG. 6.—WIRING DIAGRAM OF DUBILIER SYSTEM.

The transmitter as shown in Fig. 4 has been tried and can be successfully used as a telephonic relay, and details of these experiments will be given later.

Fig. 6 is a wiring diagram of the Dubilier Wireless Telephone System, showing the method of connecting the transmitter, from which it can easily be seen that wires, L, L, can easily be made the line wires, and so it is possible to have a telephone system consisting partly of wire and partly wireless transmission, and which may make it possible for a regular telephone subscriber to talk to a boat without any further equipment at his home.

ELECTRIC TRANSIENTS.*

BY DR. C. P. STEINMETZ.

Summary.—The author discusses, without the aid of mathematics, the electrical disturbances in high-voltage systems. He obtains two fundamental relations governing such disturbances: one the relation between the maximum current and the maximum voltage of the oscillation, and the other the transformation ratio of the voltages and currents at the transition point between two adjoining circuits.

With the increasing size and importance of electrical systems, those phenomena which temporarily occur in all electrical circuits, such as oscillations, surges, electric impulses and travelling waves, are becoming of increasing frequency and destructiveness, and a knowledge and understanding of their general nature and characteristics, and the cause of their origin, has become important and necessary for the electrical engineer. An attempt is here made to give, without the use of mathematics, a general discussion of these phenomena and their bearing on the operation of electrical systems.

The magnetic field is proportional to the current i, with a proportionality factor which is called the inductance L of the circuit, and thus is Li; the dielectric field is proportional to the voltage e, with a proportionality factor which is called the capacity C of the circuit, and thus is Ce. The energy stored in the magnetic field is $Li^2/2$, and that stored by the dielectric field is $Ce^2/2$.

Two classes of transients exist: single energy transients, in which energy is stored in one form only and the phenomenon is a steady increase or decrease of the stored energy; and double energy (or multiple energy) transients, in which, in addition to an increase or decrease of the stored energy, a transformation of stored energy between its two forms occurs, which usually is periodic.

In electric distribution circuits of 110 to 220 volts, in 600-volt railway circuits, and even in 2,200-volt primary distribution circuits, the dielectric energy is still so very small compared with the magnetic energy that the former can be neglected compared with the latter (except under special conditions, as with lightning discharges, &c). The transients of such circuits thus are single energy transients. The dielectric energy becomes comparable in magnitude with the magnetic energy in transmission lines of 30,000 volts and over, and in underground cables of 10,000 volts and over, and such high voltage circuits then give double energy transients—that is, surges of the stored energy. This is the reason for the appearance in high-voltage circuits of electrical disturbances different from those met in low and medium-voltage circuits.

The single energy transients of electric circuits, which result from the stored magnetic energy, are rarely of serious importance. Magnetic transients, however, become of serious moment when of abnormally great energy—that is, in very extended systems or in highly inductive circuits, as motor fields, and especially when forced to be of very short duration; as in the latter case, even with a moderate amount of energy, the power may be very great, since it is the energy divided by the time in which it is dissipated. The latter is the case with the opening transient of an inductive circuit. To a considerable extent an inductive circuit protects itself against too rapid opening by the arc following the switch blades. The more rapidly the switch opens the greater is the induced voltage, and the further the arc follows and maintains the circuit—that is, limits the rapidity of the circuit opening. The problem of switching inductive circuits thus is to open the circuit sufficiently rapidly to limit the burning of the switch contacts by the arc, but to open sufficiently slowly to limit the induced voltage below the value which would seriously endanger the insulation.

Occasionally magnetic transients are of importance, not directly by their stored energy, but by the power production which they cause. A characteristic instance hereof is found in the momentary short-circuit currents of alternators.

The most important, because most dangerous, electrical transients are the double energy transients of high-voltage circuits. In these circuits the gradual increase of the total stored energy, at a change of circuit conditions, is accompanied by a surge or transformation of the stored energy between the dielectric and magnetic forms. During the periodic transformation between magnetic and dielectric stored energy the magnetic energy is a maximum, $Li_0^2/2$, and therefore the oscillating current i a maximum, i_0, at the moment when all the energy is magnetic—that is, when the dielectric energy is Ce^2 and therefore the oscillating voltage e is zero. Similarly, the dielectric energy is a maximum when $Ce_0^2/2$, when during the periodic transfer of stored energy all the energy has become dielectric—that is, when the magnetic energy, and therefore the oscillating current i, is zero.

It is, however, the same amount of stored energy (neglecting the gradual and slow decrease of energy by power dissipation)

* Abstract of an article in the "Journal" of the Franklin Institute.

Digitized by Google

which at one moment appears as magnetic and at the next moment as dielectric energy—that is

$$Li_0^2/2 = Ce_0^2/2.$$

This relation between the maximum value of the oscillating current i_0 and the maximum value of the oscillating voltage e_0 is of the greatest industrial importance. It applies to all double energy transients—that is, surges of stored energy. Transposed, it gives $e_0/i_0 = \sqrt{L/C}$. $\sqrt{L/C}$ is of the nature of an impedance, and is called the natural impedance of the circuit, and may be denoted by z_0. In transmission lines, z_0 is usually between 200 and 600 ohms; it is much lower in cables, due to their high capacity and low inductance, and it is much higher in the windings of high-voltage transformers.

The importance of this relation between the maximum oscillating voltage and the maximum oscillating current is that it allows the calculation of the one from the other. In most cases of electric surges of energy one of the two quantities, the current or the voltage, is known, or can be estimated approximately from the cause of the disturbance; the above relation allows the calculation of the other.

Consider, for instance, the switching on of a transmission line at 30,000 volts. With the switches open the voltage on the line is zero; with the switches closed the voltage has an effective value of 30,000, and thus a maximum value of $30{,}000\sqrt{2} = 42{,}400$ volts. That is, at the moment of closing the circuit a sudden change of voltage occurs on the line which as a maximum can amount to 42,400. If, then, the natural impedance of the line is 400 ohms, the maximum oscillating current, which can be produced in the line by the operation of switching the dead line on to the live transformer, is

$$i_0 = e_0/\sqrt{L/C} = 42{,}400/400 = 106 \text{ amperes.}$$

Inversely, when a line carrying 30,000 volts is suddenly earthed or short-circuited—that is, its voltage changed to zero—106 amperes is the maximum current oscillation which may occur, and which, in case of short-circuit, superimposes on the wave of the permanent short-circuit current.

An interesting application of this relation is for the calculation of the maximum lightning discharge from a transmission line, against which the stations have to be protected. While the voltage of lightning may be practically unlimited, the maximum voltage which lightning can produce on the line obviously is limited by the disruptive strength of the line insulation against momentary voltages.

Assuming a 30,000-volt line, the insulators must be expected to stand continuously double voltage, or 60,000, and momentarily at least twice as much, or 120,000 to 150,000. Thus the lightning discharge current is limited to that given by the oscillating voltage of a maximum $e_0 = 150{,}000$. At a natural impedance of the line of $z_0 = 400$ ohms, this gives $i_0 = 375$ amperes.

This is the maximum discharge current which lightning could produce in this line, and thus the maximum current against which the lightning arresters in the station have to protect in case of a lightning stroke on the line near a station. If the lightning strikes at a considerable distance from the station, obviously the discharge current at the station is much less, as the energy of the oscillation is rapidly dissipated in its passage along the line.

Allowing a momentary rise of voltage at the station of 50 per cent., the maximum voltage drop across the lightning arresters would be limited to half the maximum line voltage, or 21,400 volts. At 375 amperes discharge, this allows an impedance of the lightning arrester and its discharge path of $21{,}400/375 = 57$ ohms. To afford effective lightning protection, the resistance of the lightning arrester and impedance of its connection to line and earth should, therefore, not exceed 57 ohms in this case.

The relation considered above may be applied to determine the oscillating voltage that may be produced by a sudden change of current in the line. Assuming that the full load current of the 30,000-volt line is 200 amperes effective—that is, it has a maximum value of $200\sqrt{2} = 283$ amperes. If, then, in switching off full load, the circuit were broken at the maximum value of the current, the oscillation which results would be that due to a sudden change of current from 283 amperes to zero—that is, $e_0 = 283 \times 400 = 113{,}000$ volts. This is more than double voltage, and would cause a flasher or a puncture of insulation.

Switching at or near maximum current thus is dangerous and frequently destructive, and the problem of controlling transmission lines is to devise a switching mechanism which can be relied upon always to open the circuit at zero current. This is the reason which has lead to the development of the modern oil circuit-breaker, as this type has the characteristic of opening the circuit at the zero value of the current. It also has led to the abandonment of all types of air circuit-breakers as dangerous on high voltage circuits, since the air circuit-breaker cannot be relied upon to open always at zero current, but occasionally opens at or near maximum current, and thus is liable to be destructive to the circuit insulation. The operation of the present extended high-voltage systems thus has become possible only by the development of the modern oil circuit-breaker.

The author next shows the effect of opening a short-circuit at or near maximum current. This is seen to produce the most destructive transient of a high-voltage circuit.

Occasional short-circuits, however, are unavoidable in transmission lines, and, as far as they are opened by the oil circuit-breakers in the system, they are relatively harmless. More dangerous are flash-overs on the line, resulting in flaring arcs, which lengthen and then blow themselves out. Fortunately, such flaring arcs only occasionally develop their destructive possibilities, and usually go out at the zero of the current wave. Occasionally, however, such arcs blow themselves out explosively by the rapid expansion of the air due to the heat of the arc, and as the heating effect is a maximum at or near maximum current, this explosive rupture of a flaring arc tends to occur near maximum current, and then produces a destructive oscillation. Especially is this the case in low-reactance high-capacity circuits, as cables, where the current, and therefore the heating effect in the flaring arc, is very large and the arc inherently more unstable. Such flaring arcs thus constitute the most dangerous and destructive phenomenon of high-voltage circuits.

We have seen that in the surge of stored magnetic and dielectric energy the current is a maximum when the voltage is zero, and inversely—that is, the oscillating current and the oscillating voltage, are in quadrature, and the power thus surges to and fro, but does not flow along the circuit. Such a surge of energy is called a stationary oscillation, standing wave or surge.

Oscillating current and voltage may also be in phase with each other. Then there is a flow of power along the circuit, and the phenomenon is called a travelling wave or an electric impulse. Travelling waves of high frequency frequently precede standing waves. Travelling waves have been observed of frequencies from a few hundred cycles to millions of cycles; the former by oscillograph, the latter by spark-gap across a small reactance.

In circuits comprising sections of different character, as transmission line, transformer, load, &c.—that is, in most industrially important cases—the energy surge is a combination of standing waves and travelling waves. The energy surge obviously must die down simultaneously in all circuit sections. In some circuit sections, however, as the transmission line, energy dissipation occurs at a greater rate than in other circuit sections, as transformer coils, and left separate, the surge would die down in the line much more rapidly than in the transformer. Thus, when line and transformer are connected together, energy must be supplied to the line from the stored energy of the transformer by a travelling wave. Thus in the energy surge, or the transient of such a compound circuit, a flow of oscillating power occurs between the circuit sections. This results in a transformation of the oscillating voltage and current at the transition point between the successive circuit sections.

In this connection the author shows that at the transition point between two circuit sections a transformation of voltage occurs, with a transformation ratio which is the square root of the ratio of natural impedances of the two circuit sections, and a transformation of currents by the inverse ratio. That is, $e_2/e_1 = \sqrt{z_2/z_1}$, and $i_2/i_1 = \sqrt{z_1/z_2}$, where e_1, c_1, z_1 and e_2, c_2, z_2 are the maximum voltage, maximum current and natural impedance of the line and transformer respectively.

Hence, a travelling wave coming from one circuit-section into another circuit-section of higher natural impedance increases in voltage and thereby in destructiveness; and, inversely, when entering a section of lower natural impedance it decreases in voltage. Thus, electrical disturbances originating in one circuit section frequently develop their destructiveness in adjacent sections. The result, and the indication, of a transmission line disturbance thus often is the breakdown of the transformers connected to the line, not because the transformers are weaker in insulation, but because the disturbance, while of harmless voltage in the line, has in entering the transformer risen in voltage to destructive values.

When speaking of voltage transformation at the transition point between two circuit sections, it is obvious that at the transition point the voltage is the same in both circuits, but a change of phase occurs which results in a different maximum voltage some distance further on in the circuit at the point where the voltage maximum occurs. With a voltage increase, this maximum is approximately a quarter wave distant from the transition point. Thus, transformers may break down in the middle of their winding as a result of disturbances in the transmission line to which they are connected, if the disturbance is of moderate frequency, while the breakdown would occur in the end turns if the disturbance in the line is of very high frequency. That is, the location of a breakdown in a transformer does not indicate whether the disturbance originated in the transformer or entered from the outside.

"THE ELECTRICIAN" INDUSTRIAL SUPPLEMENT.

With "THE ELECTRICIAN" for Sept. 14, 1906, was issued the first of a series of "Industrial Supplements," to be published from time to time with "THE ELECTRICIAN." The fifty-third issue of the Supplement published (Gratis) with the number of "THE ELECTRICIAN" for September 23, 1910, was the last of the monthly issues. "THE COMMERCIAL AND INDUSTRIAL SUPPLEMENT" to "THE ELECTRICIAN" is now issued weekly (Gratis). It will be found towards the end of the present issue.

NOW READY.

Vol. LXVI. of "THE ELECTRICIAN." Bound in Publisher's covers. Price 17s. 6d. Postage U.K. 1s. extra, abroad 2s. 6d.

Cases for binding Vol. LXVI. are now ready, price 2s.; post free, 2s. 3d.

THE INTERNATIONAL ELECTROTECHNICAL COMMISSION.

The meeting of the International Electrotechnical Commission which has just terminated at Turin will be remembered not only for the important decisions reached, but more especially for the very cordial relations established between the various delegates. This once again shows that to men of science there are neither national boundaries nor susceptibilities. That during the present disturbed state of international politics a Frenchman (M. R. V. PICOU) should propose the election of a German (Prof. Dr. E. BUDDE) to the highest post of honour which the Commission has to offer is, indeed, most significant.

Representatives of 19 nations were present at the Meeting, the total attendance being 52, and the discussions were carried on in French and English, the official languages of the I.E.C. (as the Commission may in future come to be known). The difficulties of translating and of formulating resolutions at such a meeting are obviously very great, and one may say without fear of contradiction that to a very large extent the success so far attained is due to the fact of the Commission having to deal with only two languages, either one or other of which was known to every delegate present. Even so, however, we understand that on one occasion the meeting was obliged to adjourn for a few minutes so as to enable the French and English texts to be unified. At the same time, it is most important to realise that the resolutions as recorded in the official languages are

Digitized by Google

not literal translations one of the other, but are rather in the nature of equivalent renderings.

It is very satisfactory to notice that both the British Government and the Indian Government were officially represented at the Meeting, which doubtless points to further recognition in the near future of the utility and importance of the work.

The decision of the delegates, taken at the unanimous and official request of the Electrical Congress, that, subject to the ratification of the various National Committees, the I.E.C. will henceforth be the sole body to authorise the holding of electrotechnical congresses should put a stop once and for all to those mushroom organisations which in the past have done so little to enhance the reputation of the electrical industry. The official standing thereby given to any future Congresses should undoubtedly be of considerable advantage; for, being organised under the auspices of the I.E.C., such Congresses will have the assistance of the national committees of every country affiliated with the movement. As more than 20 countries are now represented on the Commission, future electrical Congresses will, therefore, be international in more than name. Lest it may be thought, in connection with the above decision, that the Commission is taking upon itself unwarranted control, we would draw attention to the fact that the resolution only affects electrotechnical Congresses.

As regards the other decisions reached at Turin, we hope to give in our next issue a full account of the meetings. For the present we may mention that progress is reported under the headings of nomenclature, symbols, vector rotation and the rating of electrical machinery. With regard to nomenclature considerable progress has been made. This is due in large measure to the work of Dr. BUDDE, supported by Mr. E. BRUNSWICK (France) and Dr. S. P. THOMPSON. The recommendations of these delegates have been provisionally adopted, in the sense that, if absolutely necessary, modifications may be introduced at the meeting in 1913.

The question of symbols is one to which much attention is necessary, and it is satisfactory to know that the proposals put forward at Brussels have been adopted, with the exception that, in the case of magnetic quantities, either Script, Gothic, Clarendon or any special type may be adopted. This may possibly lead to considerable divergence of practice, but in view of the criticism levelled at the previous type suggested, the delegates could scarcely come to any other decision. As regards the use of I, E and R for current, pressure and resistance respectively, these symbols were approved with acclamation. For this decision alone the labours of the Commission are likely to prove noteworthy. Again, the international adoption of the counter clockwise direction of rotation for vectors should facilitate the work of all students of electricity—using the word "students" in the widest sense—as well as being of value to the electrical industry in general.

The last of the four main subjects under discussion was the rating of electrical machinery, and in this connection the proposals of the unofficial Conference last year were approved, and a small International Committee has been appointed to continue the study of the subject. That the American Institute of Electrical Engineers should adopt, in the new edition of their Standardisation Rules, the unofficial suggestion of the Commission last year with regard to the rating of motors in international watts is typical of the general desire to co-operate as far as possible with the Commission. This effect is likely to become more pronounced now that the Commission has given such a satisfactory record of work accomplished.

The Commission has decided to meet two years hence at Berlin, and we need scarcely say that it will receive a very warm welcome when one remembers the kindly hospitality of our German cousins. Moreover, under the guiding hand of its new and eminent President, Prof. Dr. E. BUDDE, we can safely predict further and even more important practical results of which the whole industry should feel the benefit. And, to look further into the future, the meeting in San Francisco in 1915, on the occasion of the Exhibition to celebrate the opening of the Panama Canal, is certain to be an important milestone in the history of the I.E.C. There is, however, much serious work to be accomplished before that date—spade work which will have to be carried out, to a large extent, by the small international committees appointed at Turin. In the I.E.C. we now have an impartial world's tribunal of electricians which can safely be trusted to assist the general progress of the industry by well matured and wise decisions. Certainly, the potentialities of this international co-operation can scarcely be overestimated.

REVIEWS.

(Copies of the undermentioned works can be had from THE ELECTRICIAN Office, post free, on receipt of published price, adding 8d. for books published under 2s. Add 10 per cent. for abroad or for foreign books.)

Mathematical and Physical Papers. Vol. V.: THERMODYNAMICS, COSMICAL AND GEOLOGICAL PHYSICS, MOLECULAR AND CRYSTALLINE THEORY, ELECTRO-DYNAMICS. By Sir W. THOMSON (Lord KELVIN). Arranged and revised by Sir JOSEPH LARMOR. (Cambridge, 1911: University Press.) Pp., xv. + 602. 18s.

The original intention was that the present volume should complete the collected works of Lord Kelvin. In order to do this, however, it was found that extensive omissions would have to be made, and so it was decided to run into a sixth volume. A perusal of this volume has convinced us that the decision was a wise one. We have not come across any paper that could, in our opinion, have been omitted with advantage. Notwithstanding his many and varied interests, whatever Lord Kelvin discussed he made intensely interesting.

The present volume begins with Thermodynamics, and much of the theory given is controversial. But it brings forward, in a very vivid manner, those aspects of the problem which the great physicists of the second half of last century regarded as vital. Possibly, if there were more controversies nowadays, especially if combatants like Clausius, Tait and Kelvin would join in the fray, scientific progress would be more rapid.

The Papers on cosmical and geological physics are given after the thermodynamical Papers. Such subjects as the age and rigidity of the earth, its thermal history, the duration of the sun's heat and the formation of stars and nebulæ are discussed with the energy and enthusiasm of a pioneer who has discovered new and wonderful countries. Kelvin in his early youth would have classed all these subjects under "Natural History," but in later life, in deference to conventional usage, he considered them branches of "Natural Philosophy." His conclusions may be open to question, but of the transparent honesty of his aims and the brilliancy of his achievements there can be no question. Those of us who are old enough to remember how profoundly the scientific men of the early 'seventies were roused to enthusiasm by these writings of Kelvin will always regard them as amongst the great classics of our language.

Digitized by Google

To the younger physicists, who look on the doctrine of the dissipation of energy in the same way as they look on Euclid's axioms, the reluctance of the early natural philosophers to accept it will seem strange. Sir Andrew Ramsay, the great geologist, after a long discussion with Kelvin in 1867 said: "I am as incapable of estimating and understanding the reasons which you physicists have for limiting geological time as you are incapable of understanding the geological reasons for our unlimited estimates." This attitude of some of his contemporaries explains why Kelvin was at such pains to state and restate his axioms. It was only, as he says, by sheer force of reason that geologists were compelled to admit that this world as an abode fitted for life must have had a definite beginning and must equally have a definite end.

To electricians this volume is of very special interest, as many of the papers—which the editor classes as of minor importance—deal with electrical suggestions that have borne fruit, and profoundly modified the history of the world. It is merely necessary to refer to his connection with the laying of the first Atlantic cable, to his suggestions for utilising the newly invented dynamo for lighting our towns and villages, to the transmission of power by direct current at very high pressures, &c., in order to prove that his judgment and foresight were equally admirable.

The beautiful Kelvin bridge which holds an honoured place in every electrical laboratory suggested itself at once to Kelvin when studying the theory of the Wheatstone bridge, or as he preferred to call it the Wheatstone balance. It interested the reviewer very much to learn that Kelvin invented his method of measuring the resistance of a galvanometer by applying the method of duality to Mance's method of measuring battery resistance. It is an excellent illustration of this method which is not so well known as it deserves to be.

In 1872 we find him writing to "Nature" urging makers of galvanometers, Ruhmkorff coils and electromagnets to measure the resistances of the copper wires they use in their construction. He asks them to measure these resistances in millions of centimetres per second. He suggests that the specific resistance of the copper should not exceed 16,000 gramme-centimetre-seconds. We wonder if there are many instrument makers of the present day who could interpret this specification.

In 1881 Kelvin proved the well-known rule for finding when the efficiency of a shunt dynamo is a maximum, and in the same year he showed an automatic cut-out to be used for charging accumulators. Then follows on account of the magnificent series of instruments and balances for measuring current, pressure, and power which are familiar to every electrician. Although at first sight these instruments seem to have sprung into existence in a similar manner to the way that Minerva sprang fully armed into existence out of Jupiter's head, yet his assistants can tell of the endless calculations he was always making, and the constant alterations of the designs so as to secure a still higher accuracy.

His association with Mr. Ferranti at Deptford in the early days gave rise to interesting papers on skin effect and "anti-effective" copper in cables. Many of us will remember his last public appearance at the Institution, and how he welcomed the Thury system as the realisation of his thirty-year old idea, and the generous appreciation he gave of the work of Mr. Highfield its able exponent. ALEXANDER RUSSELL.

Encyclopédie Electrotechnique. ELECTROCHIMIE. By HENRI VIGNERON. (Paris, 1911: L. Geisler.) Pp. 160.

It is a strange fact that although the number of books on electrochemistry is multiplying with extraordinary rapidity, it is very rare to find any variation in the introductory chapters. They almost all commence with a theoretical introduction in which the laws governing electrochemical reactions are more or less clearly stated. The book before us, for example, commences with a definition of first and second class conductors, then follows a dissertation upon the ionisation theory, primary and secondary reactions, other theoretical considerations such as conductivity and the law of Kohlrausch, E.M.F., and so on, and it is not until the sixth chapter is reached that one arrives at the practical part of the book. In this respect then this book does not differ to any extent from dozens of others which a reviewer comes across. The idea, of course, is to make the books complete in themselves, but it often happens that by endeavouring to do so both the theoretical and the practical parts are apt to be scrappy.

The chapter on the electrolytic processes of copper refining is quite interesting, but too much attention is given to relatively unimportant processes and not sufficient to the great industrial practice which is carried on in the United States and elsewhere. Bearing in mind the enormous quantity of copper which is electrolytically refined in the United States it is strange that the processes adopted there are passed over.

Electrolytic processes for the purification of zinc are mentioned, but there is only a passing reference to the electric furnace. We venture to think that in the near future electric furnace methods will be largely employed to obtain zinc from its ores. This book, however, does not deal at all with furnace methods; thus there is no mention of the various methods employed in refining steel; therefore one cannot take exception to the fact that the production of zinc in the electric furnace is not mentioned.

Electrolytic methods for obtaining or refining most of the metals are given, and there is a short chapter dealing with the preparation of certain inorganic salts and some organic compounds. Considerable attention is devoted to the electrolysis of common salt solutions and the preparation of hypochlorites and chlorates.

One of the most interesting and most complete sections is that dealing with the production of ozone and its industrial applications. In connection with the manufacture of ozone and the increased efficiency of the apparatus there is an interesting diagram. This shows that in 1890 the apparatus then in use, that of Berthelot, only yielded about 1 gramme of ozone per kilowatt-hour. The apparatus of Otto in 1908 yielded about 40 grammes per kilowatt-hour, and the apparatus of Gerard, brought out in 1909, yields 100 grammes of ozone per kilowatt-hour. As the efficiency of the apparatus has increased so the industrial applications of the gas have increased. Ozone is employed for sterilisation of water, for the purification of air in the ventilation of buildings, for the bleaching of oils, for bleaching flour, as a decolouriser in the sugar manufactory, to prepare certain artificial perfumes (such as heliotrope), and for a variety of other purposes.

Taken as a whole, the book gives a useful short review of electrolytic processes, and a general idea as to what is being done. F. M. P.

Wie stellt man Projekte, Kostenanschläge und Betriebekostenberechnungen für elektrische Licht- und Kraftanlagen auf? By FRITZ HOPPE. 5th Edition. (Leipzig, 1910: J. A. Barth.) Pp. xi. + 556. M. 7.

The popularity of this excellent and comprehensive German pocket-book on the preparation of estimates and working costs for electric light and power installations is well proved by the rapid succession of editions through which it has passed. The present edition is the 5th and shows several marked improvements over the 4th edition which appeared in 1907 and was reviewed in these columns in Vol. LXI., p. 257. As in the 4th edition the book is subdivided into three main sections, but these sections have been re-arranged, altered and revised, and the work as a whole has been largely extended, containing over 120 additional pages. It simply abounds in useful tables and data of every description relating to electrical matters in general (exclusive of traction), and it is well-nigh impossible to look in vain for any desired information within the domain of electric illumination and power. As already intimated in our previous review, the book is to a large extent based on the rules and regulations of the German Institution of Electrical Engineers (V.D.E.). The articles on electric illumination in Chapter I. (Part I.) are very instructive and exceedingly clear. They contain a mass of reliable information and data. Chapter II. goes very thoroughly into the question of electric motors, and includes a large amount of data of the horse-power required by all classes of industrial and domestic machines. Chapter III. is on electric cooking, heating and electro-medical

Digitized by Google

apparatus. Chapter IV. deals with electricity meters. The calculation of electric conductors and cable networks is given in Chapter V. and is very exhaustive. Chapter VI. and Chapter VII. treat respectively of electrical generating machinery (dynamos, transformers, &c.) and prime-movers (boilers, engines, turbines, gas plant, &c.) Chapter VIII. is a short one on buildings, and examples of actual estimates with explanatory notes are given in Chapter IX. which forms the last of Part I.

Part II. gives the average prices, arranged alphabetically, of dynamos, engines, apparatus, lamps, &c.; in short, everything appertaining to an electrical installation, in three chapters. The table on p. 339, giving the cost per horse-power of various hydro-electric plants, will be found most interesting.

Part III. shows how to calculate the probable working costs and to determine the revenue-earning capacity of lighting and power plants, and is very complete.

The book is certainly of great value, not only to those engaged upon the planning of electrical schemes, but to those who so often at very short notice are called upon to give a fairly close estimate of the probable cost of an installation. Of course, the prices given are those obtaining in Germany, but they will, nevertheless, be found useful. In the Appendix there are some highly interesting notes relating to the fees and allowances of consulting electrical engineers as fixed by the Verein beratender Ingenieure für Elektrotechnik E.V. in Berlin (Society of Consulting Electrical Engineers). They afford much food for reflection. Why not place these matters on some such proper basis in this country?

STUDIES IN LIGHT PRODUCTION.*

BY R. A. HOUSTOUN, M.A., PH.D., D.SC.

(Lecturer in Physical Optics in the University of Glasgow.)

(*Continued from page 901.*)

Summary.—In these studies the author deals with the theory of light production, the scope being briefly indicated by the following contents: (1) The distribution of the energy in the spectrum and the measuring of efficiency. (2) The importance of "black body" radiation and the experimental realisation of the black body. Comparison of the energy curves of a black body and of platinum, and the variation of the position of maximum energy with temperature. (3) Mechanism of flame, and the temperature, energy and efficiency of flames. (4) The Welsbach mantle and selective radiation. (5) Radiation and efficiency of the carbon glow lamp. (6) Physical properties and temperature of the arc. (7) Temperature and energy curves of the Nernst glower. (8) Efficiency of the metal filament. (9) The mercury arc and its difficulties. (10) The light of the future and the possibility of obtaining "cold light."

No. 3.—Flames.

Flames are the simplest and historically the first means of producing light. When or how prehistoric man first learned the use of fire we know not. The ancient Greeks ascribed a supernatural origin to it in the myth of Prometheus, and other legends have other legends; but it was probably obtained at first accidentally by a spark from a flint. Be that as it may, the mastery and use of fire is one of the signs that distinguish man from the brutes, and marks the first stage in the development of the artificial light of to-day.

As different stages in this development we have the primitive pine torch, the oil lamp of the ancients, which attained a great development in ancient Rome, the rush light of the Middle Ages, the different kinds of candle, from the tallow dip to the modern paraffin candle, the burning whale, seal or bear fat of the Esquimaux, the Argand lamp, ordinary coal gas and acetylene gas. In all these cases light is produced in substantially the same way—by the flame formed when hydro-carbons are burned in air. The spectra produced have in every case essentially the same character; upon the continuous spectrum of the incandescent carbon particles is superimposed the discontinuous spectra of the gaseous products of combustion, principally water vapour and carbon dioxide.

To gain an insight into the mechanism of the flame we shall therefore study as a typical case the candle, which has been made the subject of a course of six lectures by Faraday. (Michael Faraday, "The Natural History of a Candle." London 1894. Chatto & Windus.) When an ordinary paraffin candle is burning, a cup is formed at the foot of the wick. The flame melts the paraffin at the foot of the wick, while the air moving upwards by the force of the current, which the heat of the candle produces, keeps the sides cool and prevents the edge from melting. The fluid in the cup is sucked up the wick by capillary attraction. After travelling up the wick the fluid vaporises and is burned as a vapour in the flame, the heat of combustion vaporising more fluid and thus maintaining the flame. The flame travels down the wick until it is put out by the fluid in the cup. The top of the wick bends over and is consumed in the edge of the flame. In a candle, gas is manufactured for combustion just as on a large scale in the gas works of our cities.

A candle flame on examination is seen to consist of four regions. First of all there is a transparent part round the wick. It may be shown by withdrawing some through a glass tube that the transparent part consists of vapour before combustion. Below this, on the edge of the flame, there is a blue part, due to the formation of carbon monoxide. This blue part gives the Swan spectrum, and it is not known whether the latter is due to carbon or carbon monoxide. There is recent work favouring both views. Above the transparent part is the bright opaque region, which gives far the greater part of the light of the flame, and finally the flame is surrounded by a faintly luminous mantle, which in the case of the candle is somewhat difficult to see. The chemical actions occurring in the different regions of the flame are complicated and not thoroughly understood; but the bright part is due to incandescent carbon particles from the vapour after its decomposition, before they combine with the oxygen of the atmosphere to form carbon dioxide. These bright particles are carried upwards by the air current. Smoke is due to the carbon particles not having sufficient oxygen to combine with. In the Bunsen flame, on the other hand, the oxygen combines with the carbon before the latter has time to radiate as a solid.

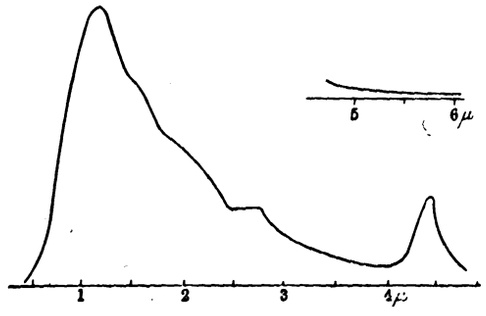

FIG. 6.

Energy curves of flames have been taken by G. W. Stewart ("The Spectral Energy Curve of the Acetylene Flame," Phys. Rev., 16, 1903, p. 123), K. Angström ("Energy in the Visible Spectrum of the Hefner Standards," Phys. Rev., 17, 1903, p. 302) and R. Ladenburg ("Uber die Temperatur der glühenden Kohlenstoffteilchen leuchtender Flammen," Phys. Zs., 7, 1906, p. 697). Stewart gives a very carefully taken energy curve of a cylindrical acetylene flame. The light was resolved by a mirror spectroscope with a fluorite prism, and the energy measured by a radiometer. The curve is reproduced above (Fig. 6).

The elevations at 1·46μ and 1·90μ are emission bands of the water vapour, and the maxima at 2·6μ and 4·4μ emission bands of the carbon dioxide in the flame, the remainder of the area being due to the glowing carbon. Stewart also gives the energy curve of an ordinary gas flame. ("The Temperatures and

All rights reserved. These contributions, amplified, will be published shortly in "The Electrician" Series.

Digitized by Google

Spectral Energy Curves of Luminous Flames," Phys. Rev., 15, 1902, p. 306.) It has the maximum at 1·13μ. Angström gives a prismatic energy curve for the amyl acetate flame of the Hefner lamp. It shows the two emission bands of carbon dioxide very clearly, but there are depressions at the positions of the two water bands, showing that more energy is absorbed by the water vapour in the atmosphere than is emitted by the water vapour in the flame. Angström uses a rock salt prism and bolometer. Ladenburg gives both the energy curves for the acetylene flame and the Hefner lamp, taken with a mirror spectroscope, quartz prism and thermopile, but not so far into the infra-red. Both his curves show the absorption bands of water, and in the Hefner lamp curve the carbon dioxide band nearer the shorter wave-lengths—the only carbon dioxide band shown—appears as an absorption band. The maximum of his acetylene flame is at 1·21, and its shape does not agree well with Stewart's curve.

The temperatures of the acetylene, gas and candle flames have been measured by E. L. Nichols ("On the Temperature of the Acetylene Flame," Phys. Rev., 10, 1900, p. 234) with a platinum platinum-rhodium thermo-element. The introduction of a thermo-element into the flame lowers the temperature of the flame. Four different thermo-junctions were, therefore, used, made of wires of different diameter. The thinner the wire the higher was the temperature recorded; hence by plotting the temperature as a function of the diameter of the wire and continuing the curve he found what temperature would be recorded by an infinitely thin wire. The determination was also complicated by soot forming on the junction and lowering its temperature, and, in the case of acetylene, by the junction melting. The thermo-element was gradually pushed into the flame and the readings plotted as a function of the distance from its centre until the junction melted or soot began to form. Then the portion of the curve found was simply produced to the centre of the flame. In this way the centre of the luminous region of the acetylene flame was estimated to be at 1,900°C., while the sheath surrounding the luminous region may be 20°C. higher. The luminous region of the gas flame was found to be not more than 1,780°C., and the hottest portion of the candle flame to be 1,670°C. From the diagram given the average value for the luminous region of the latter is probably 100°C. lower. In standardising his thermo-element Nichols took the melting point of platinum as 1,775°C.

Assuming that the carbon in flames radiates more selectively than a black body and less selectively than platinum, and using the formulæ established by Lummer and Pringsheim for the maximum of the energy curve in these cases—namely,

$$\lambda_m T_{max.} = 2{,}940,$$
$$\lambda_m T_{min.} = 2{,}630,$$

we obtain the following results:—

	λ_m	$T_{max.}$	$T_{min.}$
Candle	1·5	1,687°C.	1,477°C.
Argand lamp.....	1·55	1·627°C.	1.427°C.
Acetylene flame ...	1·05	2,527°C.	2,232°C.

The formulæ give the temperatures in degrees abs., but in the table they are expressed in degrees cent. $T_{max.}$ is the temperature which the flame would have if we assume that it radiates as a black body, $T_{min.}$ if we assume that it radiates as platinum.

The value thus obtained for the temperature of the acetylene flame is very much higher than Nichols' value. Stewart states that he considers it much too high. Kurlbaum suggests the cause of the difference (Phys. Zs., 3, 1902, p. 187). While a luminous flame of very great thickness may be expected to radiate as a black body, yet we may expect a candle flame to radiate as a very thin film of soot at that temperature. Now lamp black is more transparent to long waves than short waves—*i.e.*, the absorption and radiation increase with decrease of wave-length. Hence on applying the formula $\lambda_m T = \text{const.}$ the temperatures obtained will be too high, for the maximum will be much further towards the short wave-lengths than in the case of a black body at the same temperature. Thus, according to Kurlbaum, the radiation of glowing carbon is usually more selective than that of bright platinum.

This has been proved by Ladenburg (loc. cit.). As has been already stated, he took an energy curve of the acetylene flame and of the Hefner lamp. He then caused the light from a Nernst glower to pass through these flames and plotted the percentage absorbed as a function of the wave-length, thus determining the absorption as well as the emission of the flame. The absorption of both flames increases as the wave-length decreases. If now we divide the emission by the absorption we obtain the emission of the theoretical black body at the same temperature. As a final result, Ladenburg obtains 1,838°C. for the acetylene flame and 1,431°C. for the Hefner flame. He states that Nichols' value of the melting point of platinum is 55°C. too high. The latter's value for the centre of the flame should thus be 1,845°C., which is in very good agreement with his own.

Stewart (loc. cit.) finds the radiant efficiency of the acetylene flame to be 0·039. The result was obtained by dividing the area of the energy curve to the left of 0·76μ by its whole area. K. Angström had previously found it to be 0·055. K. Angström has also made a very careful determination of the radiant efficiency of the Hefner lamp by an original method. He first took the energy curve, and found that, in the visible spectrum and in the infra-red as far as 1·5μ, it agreed with the curve of a certain glow lamp for one particular current. By means of a prism and screen the light from the glow lamp was separated from its heat rays. After the heat rays were separated out the light rays were allowed to come together again and fall on one face of a wedge photometer on the other face of which the light from a Hefner lamp fell, and the distance of the latter adjusted until balance was obtained. The photometer was then removed and a bolometer placed in exactly the same position. The intensities of the two beams were then measured in succession by the bolometer; their ratio gave the radiant efficiency. The value found was 0·0096.

For an oil lamp with glass funnel W. Wedding finds 0·01 by the water-filter method.

So much for the radiant efficiency—the ratio of light emitted to total radiation. But the question arises of the luminous efficiency—the ratio of the light emitted to the total energy consumed. In order to determine the latter we require the total radiation in absolute measure, the rate at which the substance is being burned and the calorific value of its unit mass. For the case of the Hefner lamp the ratio of the whole energy radiated to the energy consumed has been calculated by O. Tumlirz, and we take the following details from his article ("Die Wärmestrahlung der Wasserstoffflamme," Wien. Ber., 113 (Abt. II.a), 1904, pp. 501-509). The energy received by a surface element at a distance of 1 metre from a Hefner lamp is $1{\cdot}62\ 10^{-5}$gm. cals. per square centimetre per second, the surface element being normal to the straight line joining it to the flame and the latter line being horizontal. K. Angström (loc. cit.), it may be noted, found $2{\cdot}15\ 10^{-5}$ gm. cals. per square centimetre per second for the same quantity by means of his pyrheliometer. Hence in a second the flame radiates $4\pi \times 10^4 \times 1{\cdot}62\ 10^{-5} = 2{\cdot}04$ gm. cals. The quantity of amyl acetate burned in a second is 0·002678 gms. According to Favre and Silbermann the heat of combustion of 1 gm. of amyl acetate is 7,971·2 gm. cals.; hence the heat given out by the Hefner lamp in one second is $7971{\cdot}2 \times 0{\cdot}002678 = 21{\cdot}35$ gm. cals. We arrive, therefore, at the result that the ratio of energy radiated to energy consumed is 2·04/21·35, or 0·096. The greater part is lost by convection. If we assume Ångström's value for the radiant efficiency—namely, 0·0096, the luminous efficiency becomes $0{\cdot}0096 \times 0{\cdot}0956 = 0{\cdot}00092$. That is, the efficiency of the Hefner lamp as an energy transformer is less than one-tenth per cent. There is no reason to believe that our ordinary illuminating gas is any better.

In the same article, Tumlirz describes a determination of the ratio of the total energy radiated to the energy consumed by a hydrogen flame. The value found was 0·0615.

THE ELECTRICAL EQUIPMENT OF THE CRAIGHEAD AND BOTHWELL CASTLE COLLIERIES.

These collieries, which are amongst the oldest in Scotland, are situated at Bothwell Castle near Glasgow, and are owned by Messrs. William Baird & Co. The experience of this firm, who were one of the first in Scotland to adopt electricity for underground mining work, has been such that they are now one of the firmest advocates of the electric drive.

In the present article it is intended to deal with the power equipment rather than with the actual work carried out. The power house is situated at the Bothwell Castle Colliery, and a portion of the output is transmitted at a pressure of 8,200 volts to Craighead Colliery, a distance of about a mile. At a later date power may be transmitted to other collieries in the same way.

The generating plant at present comprises a mixed-pressure straight-flow turbine of the Westinghouse impulse type, direct-coupled to a 300 kw. 500-550 volt three-phase 50-cycle turbo-alternator with coupled exciter. The turbine takes exhaust steam from two engines, one driving a fan and the other a haulage. The

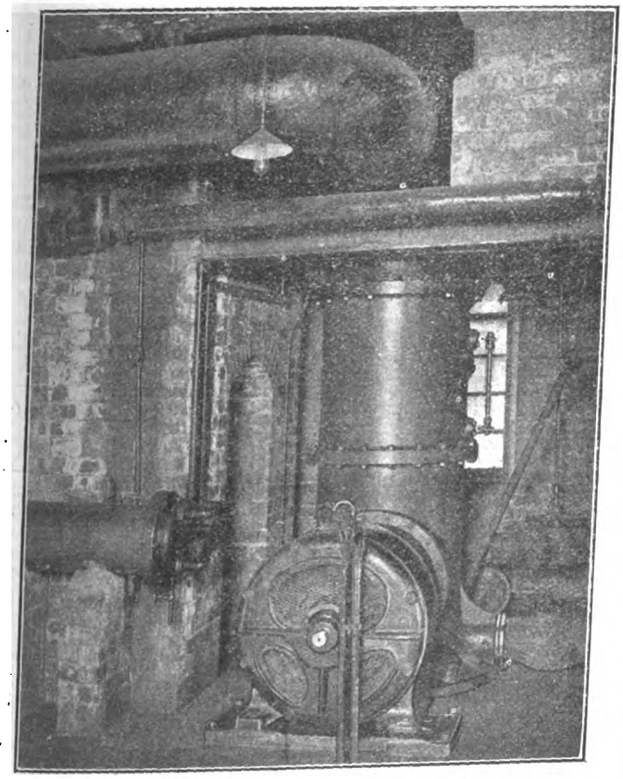

FIG. 1.—WESTINGHOUSE LEBLANC MULTIPLE JET CONDENSING PLANT DRIVEN BY 47 B.H.P. SQUIRREL-CAGE MOTOR.

amount of power thus available is from 115 to 180 kw., and when this supply is insufficient to carry the load, live steam is taken from the boilers at 60 lb. per sq. in. pressure, regulation being effected automatically.

The condensing plant, which has an average duty of 12,000 lb. of steam per hour, is of the Westinghouse-Leblanc multiple jet type, and is capable of maintaining a vacuum of between 27½ and 28 in. of mercury at full load, the air and circulating pumps being driven by a squirrel-cage motor rated at 47 B.H.P. at 720 revs. per min. (*see* Fig. 1). This motor, which with the condenser is situated in the basement, is controlled from the engine room by a mining type control pillar, comprising oil switch, oil immersed controller and ammeter. The water and vacuum gauges are also mounted on this pillar, the whole forming a remarkably complete and accessible control system.

The current generated is used at the terminal pressure at Bothwell Castle on motors both above and below ground, but is transformed to 2,200 volts for transmission to Craighead. The line is designed for working later at a pressure of 6,600 volts, but as all the electrical machinery has not yet been erected the lower voltage is quite sufficient for the small amount of power at present being transmitted.

A six-panel black-enamelled slate switchboard controls the generator and outgoing feeders, and comprises one high-tension and five low-tension panels. One of the latter is for the main generator and carries the main oil switch, exciter switch, ammeters and voltmeters. A "Summation panel" carries a wattmeter, power-factor meter, milliammeter and watt-hour meter.

There are three low-tension feeder panels for station supply, surface, and underground feed respectively, two of which carry oil switches and ammeters. The other is mounted with a three-pole

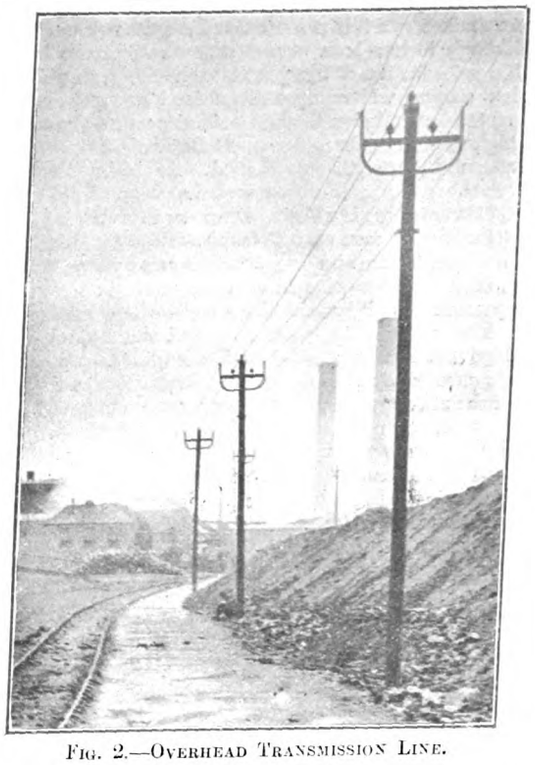

FIG. 2.—OVERHEAD TRANSMISSION LINE.

knife switch for the condenser motor, and a two-pole switch, fuses and ammeter for the lighting circuit. On the high-tension panel there is a voltmeter and an ammeter, two static ground detectors, and a high-tension oil switch. The panels are fitted with pilot lamps to indicate whether they are "live" or not.

Current is taken from the high-tension bus bars and led underground by a three-core paper-insulated lead-covered cable to a

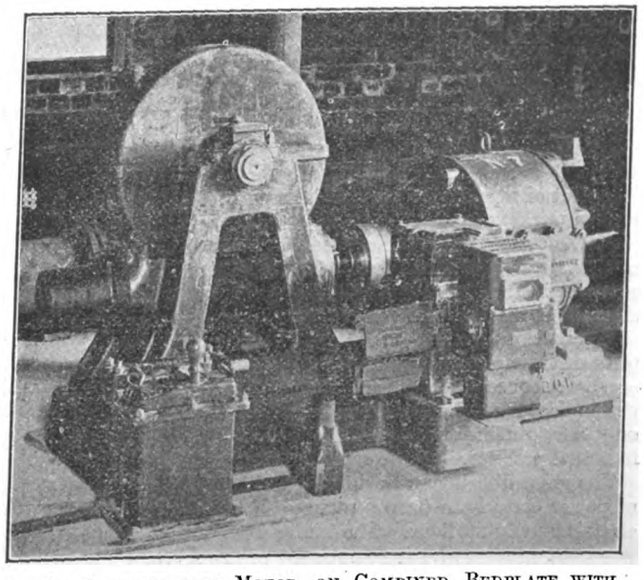

FIG. 3.—SQUIRREL-CAGE MOTOR ON COMBINED BEDPLATE WITH WORM-DRIVEN HAULAGE GEAR.

point clear of the Bothwell Castle works, and thence by an overhead aluminium line, supported at intervals of about 50 yds. on wooden poles, to Craighead, where it is stepped down to 500 volts for use.

This line is led across country over road and woods, finally crossing the river Clyde at a point where it is 210 ft. wide. A view of the overhead aluminium line is given in Fig. 2. The line was tested at

F

Digitized by Google

11,000 volts to meet the Board of Trade requirements, and was found perfectly satisfactory in every way. It is composed of three aluminium cables, each consisting of three No. 10 S.W.G., and having no joint from end to end. These cables are fastened by aluminium clips to brown porcelain insulators, the latter having been tested to 22,000 volts.

At the Clyde, steel guard wires are fixed underneath the lines for the double purpose of taking the pull and preventing the lines from falling in the event of a break. A high-tension telephone line connects the two mines, and it is mounted on the same poles as the power lines. Although it has been stated that the pressure is stepped down to 500 volts for use at Craighead, it should be mentioned that high-tension current will be used direct for large motors, and will also be used for transmission to other collieries where the supply will be direct high-tension to the motors. At Bothwell, Nos. 1 and 2 pits, 500-volt alternating current only is used. At present there are five motors in use at the former and seven at the latter, all of the squirrel-cage type. One of these is a 7 H.P. motor used for driving a winding equipment for hauling men up a 25 ft. pit.

At the Bothwell Castle and Craighead pit some very neat haulages are in use, motive power being furnished by two-speed squirrel-cage motors, operated by oil-immersed controllers and mining type oil switches. The drive is by worm gear, and the motors, which are rated at 10-5 H.P. run at a speed of 970-480 revs. per min. This variation is effected by a controller which makes the different connections of the stator winding so as to vary the number of poles, the minimum number of poles giving the maximum speed. A view of one of these motors is given in Fig. 3.

This plant represents practically the last word in colliery work and reflects great credit on Messrs. Stevenson & McGuffie (consulting engineers to Messrs. William Baird) and also on the British Westinghouse Electric & Manufacturing Co., who are responsible for the entire electrical equipment.

THE DIESEL OIL ENGINE.*

BY CHARLES DAY.

Summary.—The author gives two tables based on the published costs of electric supply stations. These tables show the comparative cost per unit sold for steam, gas and Diesel plant up to 1,000 H.P. capacity; and, secondly, the effect of the size of steam plant on the cost of generation. The main features of the Diesel engine are also discussed.

The economical generation of power for industrial purposes depends mainly upon the following factors:—

1. (*a*) The attainable economy of working at different loads of the prime mover itself, including boiler or gas-producer, and all accessories, such as condensers, feed pumps, water pumps, &c. (*b*) The degree to which this attainable economy can be practically maintained under the conditions of working, and the load factor.

2. The stand-by losses *i.e.*, the expenditure necessary to keep the plant ready for work when wanted.

3. Wages of engine-room attendants, stokers and other men employed about the power house.

4. Expenditure on lubricating oil, cleaning waste and sundry stores.

5. Cost of repairs and the maintenance of all parts of the plant in good working condition.

6. The cost of water for condensing, and for boiler feeding in the case of steam plant, for the engine water jackets, and for the gas-producer in the case of gas plant, or for the engine water jackets in the case of Diesel plant.

From the mere enumeration of these items it is very obvious that tests either on makers' works or on site, even though the tests extend over a week or so, do not form a sufficient guide as to the real value of the engines for industrial purposes, and that a far safer, in fact, the only safe, conclusion can be formed from a study of results obtained in actual practice.

The great difficulty most buyers find is in securing reliable figures of power costs from people engaged in trade, except in the case of electric supply stations. The writer does not know of any body of large power users who systematically prepare accounts showing their power costs on a uniform basis, and publish them. This practice in connection with electric supply stations fortunately does give an independent and authoritative basis, from which valuable deductions can be made. From the figures published in the "Electrical Times" the author has determined the following average results with different types of plant for stations having a plant capacity not exceeding 1,000 H.P.

* Abstract of a Paper read before Section G of the British Association at Portsmouth.

Table I.—*Average Cost in Pence per Unit sold.*

Type of engine.	Fuel.	Lubricating oil, waste, stores & water.	Wages.	Repairs & maintenance.	Total works cost.	Load factor.
Steam	0·45	0·06	0·25	0·26	1·02	14·7
Gas	0·43	0·09	0·28	0·24	1·04	15·3
Diesel	0·23	0·04	0·19	0·07	0·53	14·3

The limit of 1,000 H.P. was fixed owing to there being as yet no large electricity supply stations equipped solely with Diesel engines or gas engines. Of course, better results are obtained when driving machinery which gives a better load factor, but the causes which produce loss are, as a rule, the same, though modified in extent. The general conclusion formed from a study of electricity stations holds good for the great majority of power users, though perhaps not applicable to some special trades, where engines can be run continuously on almost uniform loads. It is also necessary to point out that the figures include some items which should not strictly be charged against the power plant. For instance, the wages items include figures for men working on cables, street lamps and in sub-stations, whilst the repairs items include repairs to such parts. Also it is necessary to mention that the figures give the costs per unit sold, and not per unit generated.

From the averages it is clear that a substantial gain is obtained by the adoption of Diesel engines as against either gas or steam engines, the figures being beyond doubt substantially accurate. It is also noticeable that the gain is not only on fuel consumption, but is practically in the same proportion on the other items of expenditure. The great saving shown by these average figures is confirmed by repeated experiences of the author.

When going through costs records to prepare the average figures previously given, the author noticed very wide differences of cost per unit, particularly in the case of the steam plant. He, therefore, had the average cost calculated for steam stations of different capacity, and as the results are interesting, they are given separately in Table II.:—

Table II.—*Average Works Cost in Pence per Unit sold for Steam Stations of Different Sizes.*

Stations not exceeding	Fuel.	Lubricating oil, waste, water & stores.	Wages.	Repairs & maintenance.	Total.	Load factor.
250 kw.	0·63	0·09	0·35	0·36	1·43	13·2
500 ,,	0·56	0·06	0·27	0·29	1·18	13·3
750 ,,	0·43	0·05	0·23	0·24	0·95	15·4
1,000 ,,	0·40	0·05	0·23	0·21	0·89	16·8
1,500 ,,	0·42	0·04	0·17	0·18	0·81	16·9
2,000 ,,	0·37	0·04	0·16	0·21	0·78	17·7
3,000 ,,	0·33	0·04	0·15	0·17	0·69	17·4
4,000 ,,	0·40	0·03	0·14	0·20	0·77	18·8
5,000 ,,	0·34	0·03	0·11	0·16	0·64	18·7
7,000 ,,	0·36	0·04	0·13	0·20	0·73	17·9
10,000 ,,	0·26	0·03	0·09	0·13	0·51	22·6
20,000 ,,	0·30	0·03	0·11	0·16	0·60	19·6
50,000 ,,	0·23	0·02	0·10	0·11	0·46	20·56

This table shows the great improvement which follows increase of size with steam stations, or, expressed in the reverse direction, it shows how great is the disadvantage of small stations when steam power is used.

It is, further, to be noted that, even with the largest steam stations, the costs per unit generated are no better than for quite small stations using Diesel engines, and this in face of the improved load factor. This is a most important point, and shows that small Diesel stations can profitably supply current at prices hitherto thought to be obtainable only in densely populated centres having large power stations.

In all cases the figures which have been given are works cost, and do not include anything for interest on capital or depreciation. It is hardly possible to give a definite statement showing the cost of constructing and equipping power houses of different types, as there are so many variable factors. However, the author's experience of a considerable number of estimates indicates that up to a capacity of, say, 1,000 kw., there is generally little difference between the gross capital expenditure required, whether steam, gas or Diesel engines be adopted.

Having now dealt with what may be termed the commercial aspect, it may be well to study briefly the constructional features desirable in engines for dynamo driving. In the first place the dynamo should be coupled direct to the engine shaft, and not be driven by belt or ropes, as the up-keep cost of these is considerable; also, with belt or rope drive, the space occupied is considerable. Direct coupling of dynamos means that low-speed engines are to be avoided, otherwise the cost of the dynamos is very high. For speeds

Digitized by Google

which are not low, engines of the multi-crank type become desirable, otherwise serious vibration is likely to be caused. For the same reason it is important that the distance between the centre lines of the cylinders of an engine be reduced as much as possible. If far apart, as, for instance, in the case of a cross-compound steam engine with dynamo between, then each cylinder or line of parts will produce its own vibrating effects on the foundation without being materially influenced or counteracted by the other. For multi-crank engines with cylinders close together the vertical construction is much more suitable than the horizontal, and gives much better accessibility. Also, any unbalanced inertia forces do not tend to slide the engine about, but merely increase or decrease the weight on the foundations.

The vertical design is also better from the point of view of piston wear. Multi-crank engines are also advantageous as regards speed regularity during each revolution, and when high-speed engines are adopted, the multi-crank vertical type becomes imperative.

There is another point in regard to the multi-cylinder design of engine which should be mentioned—viz., that with this design a smaller diameter of cylinder is required for a given power than with a single-cylinder engine. With internal-combustion engines this is of great importance, as after a certain size every enlargement of cylinder diameter brings with it increased constructional difficulties and a greater liability to breakdown.

Turning next to the particular features of the Diesel engine itself, the author describes briefly the development of the present Diesel cycle.

The cycle enunciated by Carnot in 1824 appears quite an impossible one, because during the one portion of the compression heat must be perfectly carried away—*i.e.*, the working fluid and the surrounding materials must be perfect conductors. Then during the second portion of the compression no heat must be carried away or added, meaning that the materials must now be perfect non-conductors. With these opposing conditions it is not surprising that no application of the Carnot cycle appeared in practice for so long. Diesel, however, propounded a scheme which, to a certain degree, met the Carnot conditions. This scheme was as follows :—

The isothermal period of compression was obtained approximately by spraying water into the cylinder during compression, this water spray being discontinued for the adiabatic compression. For the isothermal expansion fuel-oil was sprayed in to give the requisite addition of heat. The spraying in of fuel-oil for this purpose necessitated the adiabatic compression being carried to a high degree, so as to give a sufficiently high temperature to the air in the cylinder as to cause ignition of the oil sprayed in. Unfortunately, this cycle did not meet with success in practice owing to the very high pressure required, and to the small amount of work obtained, and gradually the original cycle has become modified to that now adopted, which may therefore be claimed to be the nearest to the Carnot cycle that present-day practical limits admit. Briefly it is as follows: (1) During the suction stroke air is drawn into the cylinder. (2) During the compression stroke this air is compressed to a considerable pressure and temperature. (3) For a short period during the next stroke oil is sprayed into the cylinder, and burns in consequence of the high temperature to which the air has been raised by compression. During the remainder of the stroke expansion takes place. (4) The products of combustion are exhausted.

The heat efficiency of the Diesel engine, though far from perfect, is still much better than any other heat engine, as is readily seen from the fuel consumption, which is 0·44 lb. of fuel oil per brake horse-power per hour. The fuel consumption is also low at partial loads, viz. :—

¾ load	0·45	lbs. per	B.H.P. per hour.
½ ,,	0·47	,,	,, ,,
¼ ,,	0·62	,,	,, ,,

These are every-day figures, and are for engines of quite moderate size. With larger engines the fuel consumption per horse-power is rather lower, but increase of size does not give anything like the improvement in fuel consumption that occurs with steam engines. This is a point to be remembered when fixing the size of engine to be adopted in a station.

Owing to the high economy at light loads it is often found distinctly advantageous to run a Diesel engine in preference to using a storage battery.

The fuel oil used can be almost any of the fuel oils which are used for boiler firing, and a wide variety of oils can be used with no alteration of the engine. The use of oil fuel carries with it certain advantages in the way of ease in handling and of cleanliness. With coal it is difficult to avoid dust, and this must be particularly objectionable in the case of steam plant, where the engines are carried on the boilers, thus placing a considerable quantity of moving machinery in the neighbourhood of the coal. With oil there are no ashes to cart away, and thus handling of gritty materials is entirely eliminated. Usually the oil is pumped from an outside storage tank to the small tanks near the engines.

The question may naturally be asked whether Diesel engines are suitable for long periods of continuous running. In reply to this the following instance may be quoted :—

At the Birkdale electricity works a "Mirrlees Diesel" was put down a little over four years ago. The station engineer recently made a return which showed that the engine had, on the average, worked 23¾ hours out of every 24 hours throughout the four years, or an average stoppage of about 1¼ hours each Sunday.

Numerous cases could be given of large savings effected, but the figures already given substantially prove this.

Diesel engines of the Mirrlees make have been fitted on board many warships and first-class cruisers, for driving dynamos; also, some have been used for boat propulsion. It might be of interest to mention that the first Diesel engine made in Great Britain was a Mirrlees Diesel engine, and was made over 14 years ago, consequently the present Mirrlees Diesel engines represent quite a long experience; and the present appreciation of this engine is not a temporary boom, but is based on substantial experience.

A MECHANICAL LAMP-TESTER.

An interesting device which we show in the accompanying illustrations is a mechanical lamp-tester. It was invented by M. Vincent, one of the engineers of the Western Railroad Department of Paris, and it is designed for testing incandescent lamps by subjecting them to repeated shocks. In this way it is desired to imitate as nearly as possible the treatment which the lamps would receive when used on

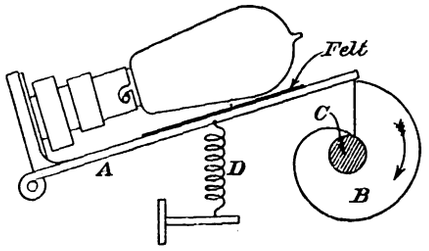

Fig. 1.—Diagram of Lamp Tester. (General Arrangement.)

railway trains, and thus to find out their weak points, and to improve their manufacture by selecting the types which will withstand shocks the best. Some device of this kind is specially needed for metal filament lamps, for as yet such lamps have not been used extensively for train lighting, at any rate in France, on account of their frâgility. For instance, a correspondent informs us that on the new North-South Paris subway metal filament lamps are used for lighting the stations, but carbon filament lamps are retained for lighting the cars.

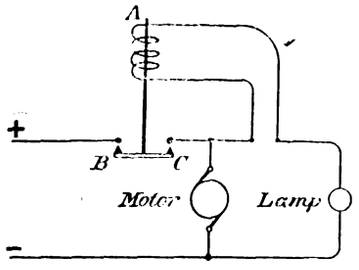

Fig. 2.—Connections for Hot Test.

M. Vincent states that he is endeavouring to get manufacturers to improve metal filament lamps in the directions indicated by the results of tests with his apparatus. Thus he hopes finally to secure a suitable type of lamp for train lighting.

The device used for the purpose is of the simplest form, as will be observed by reference to the illustrations. The lamp (Fig. 1) is fitted into a socket which is mounted upon a small board, A, hinged at one end, while the other end is movable and is actuated by a cam, B, fixed to the shaft C. Each time the cam revolves, the end of the board is dropped down, thus giving a definite shock to the lamp. By means of a spring, D, the amount of this shock can be adjusted and made heavy or light. The shaft is driven by a small electric motor, and carries at its further end a counter, so that the number of revolutions can be read off.

For testing the filament when burning normally or otherwise heated by the current, the method shown in Fig. 2 is used. Current

Digitized by Google

from the mains first passes to the motor and to the lamp which is in parallel with it. In series with the lamp, however, is a solenoid, A, of very low resistance. This solenoid normally holds up the main switch BC, but should the lamp filament break the current through it will fail and the core will drop, and thus open the switch in the motor circuit. The motor then stops, and the number of shocks which the lamp has stood can be read off on the counter.

In order to test the lamp when the filament is cold, the following method is employed: A small current is passed, which simply acts as a detector, and shows whether the lamp is broken or not. In this

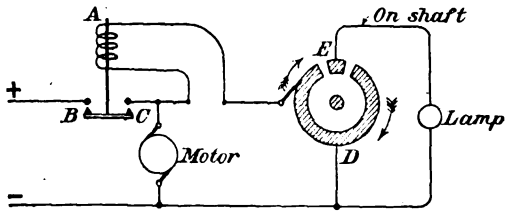

FIG. 3.—CONNECTIONS FOR COLD TEST.

case, too, the current is passed through the lamp for a short time during each revolution. The same apparatus as that described above is used except (*see* Fig. 3) for an extra rotating contact maker, which carries a long segment, D, and a short segment, E. For the greater part of a revolution the current passes through the solenoid and not through the lamp, and for a very short time it passes through the solenoid and the lamp in series. The time is too short to cause the lamp to become heated by the current, and the solenoid normally keeps its core held in position. Should the filament be broken, the current fails in the solenoid for an instant, and this suffices for the core to drop and open the switch. In any case the apparatus goes on working without needing any attention, so that it can be left to itself and the number of shocks is always exactly recorded at the end of any length of time.

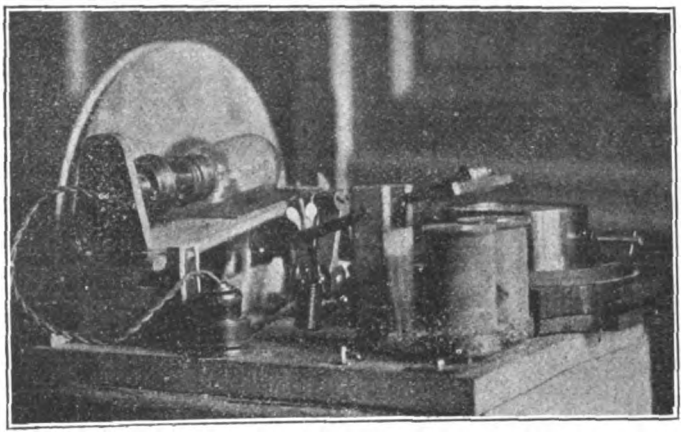

FIG. 4.—VIEW OF LAMP TESTING DEVICE.

HOMOPOLAR GYROSTATS.

At the Electrical Exhibition which is just about to open at Olympia visitors will have an opportunity of seeing a gyrostat which is driven by a homopolar motor. The exhibit is by Messrs. Homopolar Machines, of London. It is a common thing to drive gyrostats by ordinary continuous-current motors, but as the speed must usually be high such motors are not very suitable; special construction must be adopted, and if they are run in vacuo there may be trouble from flashing over at the commutator. These difficulties are avoided in the present apparatus by making the gyrostat wheel the rotor of a homopolar motor, a couple of slip-rings being then the only electrical connection.

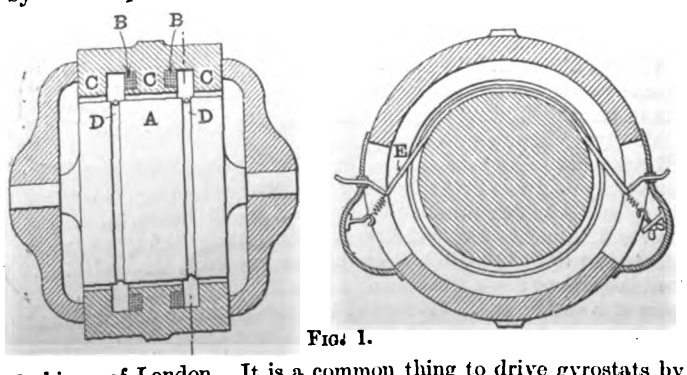

FIG. 1.

There are two ways of doing this as indicated in Figs. 1 and 2. In the first the gyrostat wheel is absolutely simple, without any insulation, and is indicated at A in Fig. 1. The stationary poles C are produced in the casing by two annular windings B. Current is led in and out of the flywheel by flexible cord brushes E, which lie in the grooves D. If preferred, one brush may bear on the periphery of the flywheel and the other on the shaft or transmission.

In Fig. 2 the arrangement is such that the flywheel carries the magnetising coil B, and the current to this is supplied by a brush running in the groove A (one end of the coil being earthed to the wheel), and a second brush running on a slip-ring C to which the other end of the coil is connected. The coil is preferably wound as a volute with flat copper strip, the broad faces of the strip being in contact so that the centrifugal force has no tendency to cut insulation or to force any part of the coil on sideways. The flywheel is shown as in one piece, but it is preferably built up of different qualities of steel, that of high tensile strength being used where strength is important, whereas a ring of high permeability iron is used where necessary for the magnetic circuit.

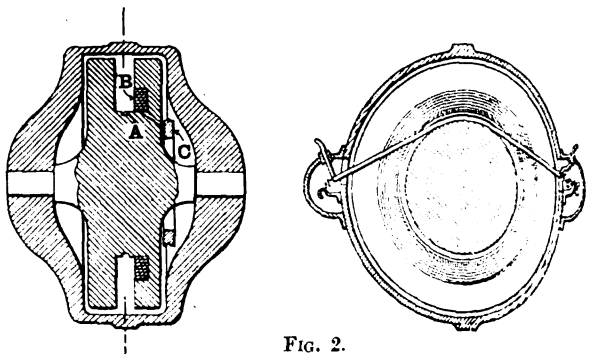

FIG. 2.

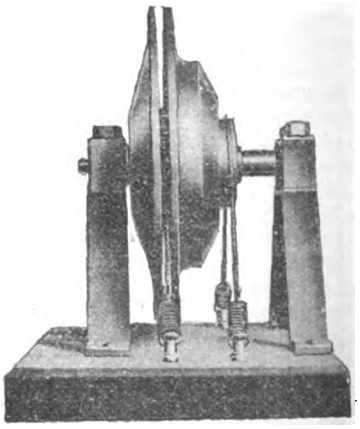

FIG. 3.—VIEW OF HOMOPOLAR GYROSTAT.

The outer casing shown in Fig. 2 is only fitted to enable a vacuum to be obtained; it has no electrical use, so that the whole *motor* revolves, excepting only the brushes. This is more clearly shown in Fig. 3, which is a photograph of an actual model shown at the Electrical Exhibition. The patentees are Messrs. R. H. Barbour and E. Kilburn Scott.

OERLIKON EXTRA HIGH PRESSURE TEST TRANSFORMERS.

The voltage of modern high-tension transmission schemes has gradually increased year by year, and it is to-day quite a common thing to work at a pressure of 60,000 volts or above. Since machines, transformers, insulators, cables, switchgear, &c., have generally to be tested under twice and three times the normal working pressure the tendency to use higher pressures has, therefore, necessitated the designing of transformers for pressures of 200,000 volts and higher.

The Oerlikon Co. have constructed a large number of such apparatus. The illustrations herewith show some of the transformers constructed at the Oerlikon Works. These transformers have horizontally placed cores, and are provided with oil cooling.

A series of such transformers is at the present moment in course of construction at the Oerlikon shops. These transformers have been

Digitized by Google

designed for the testing of insulation materials, mainly porcelain, and we are informed that those which have been in use for some 1½ to 2 years are giving excellent results.

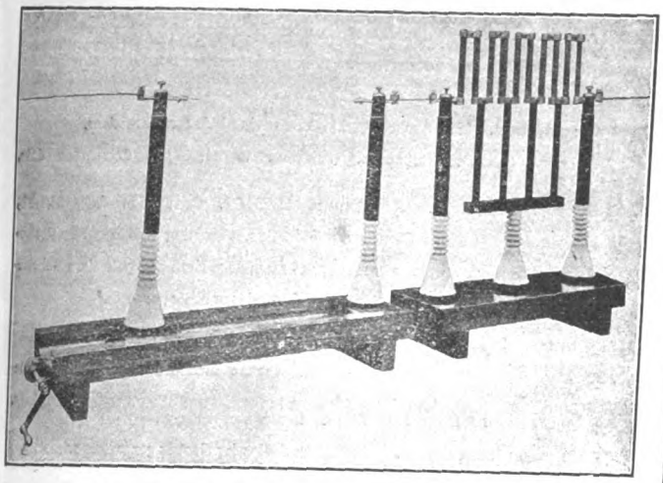

FIG. 1.—SPARK GAP WITH NON-INDUCTIVE RESISTANCE IN SERIES.

It is not difficult to manufacture transformers which can stand for a short time the extra high pressure above referred to, but when they are kept constantly under this pressure it is by no means a rare occur-

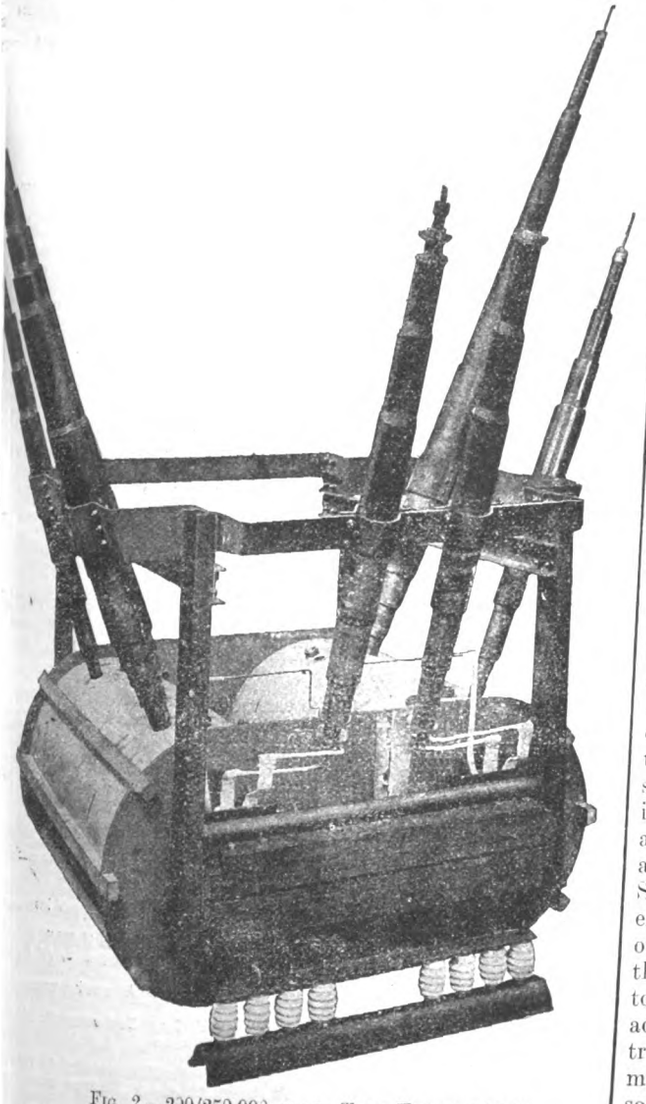

FIG. 2.—200/250,000 VOLTS TEST TRANSFORMER.

rence for brush discharges to develop. Lengthening discharge paths gradually ensue, ultimately resulting in short-circuits. It is, therefore, of particular interest to note that the Oerlikon Works claim that their transformers can operate continuously under the maximum pressure without experiencing such troubles.

For measuring and limiting the pressure in connection with such transformers, the Oerlikon Works use a carefully calibrated spark-gap, with a large non-inductive resistance in series, arranged as shown in Fig. 1. The resistance damps the surges when using the above air-gap.

Fig. 2 illustrates a 25 k.v.a. 200/250,000 volts 50 frequency test transformer, whilst Fig. 3 shows the construction of a 250 k.v.a.

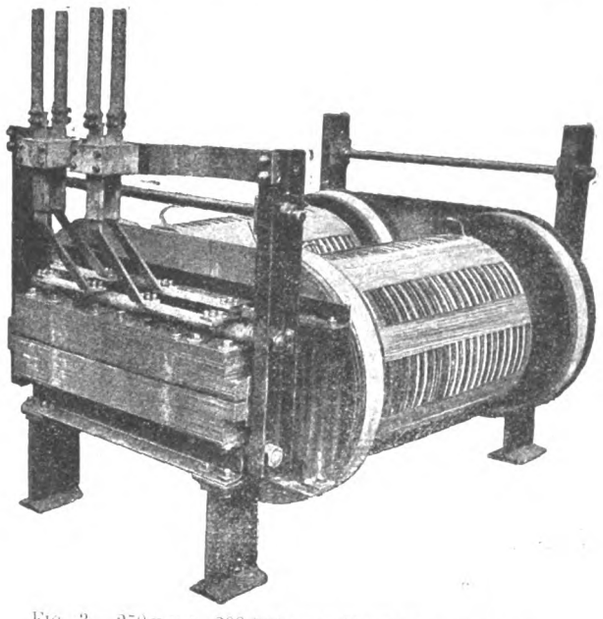

FIG. 3.—250 K.V.A. 200,000 VOLT TEST TRANSFORMER.

transformer for increasing the pressure from 140 to 200,000 volts at a frequency of 50 cycles.

Further particulars can be obtained from Mr. G. Wüthrich, manager of the London branch of the Maschinenfabrik Oerlikon.

ATLANTIC CABLE MATTERS.

We were able to give last week some brief particulars of the arrangement arrived at by the Anglo-American and the Western Union Telegraph Companies in the matter of the fusion of interests which the directors of these companies have been negotiating for some time past. We are now in a position to state that similar arrangements have been made between the Direct United States Cable Co. and the Western Union Co. This arrangement provides that the Direct Co. shall lease to the Western Union Co. for a term of 99 years, as from April 1 last, its cables, telegraph lines, offices, landing places, plant, stores, &c., at an annual rental of £58,568, the period between April 1 and June 30 this year being a matter of a separate item of account. In the case of the Anglo Co. the Western Union takes over all the employés other than those required in the secretary's office at existing rates of pay, terms and conditions, including the benefits under the Anglo Company's Pension and/or Endowment Assurance Scheme. Arrangements are also made which provide for the upkeep of the Anglo Company's Staff Pension Fund. The Western Union Co. also pays the expenses of administering the affairs and maintaining the organisation of the Anglo Co. along with a contribution towards the directors' fees. In the case of the Direct Co., in addition to the rental, the Western Union Co. provides the cost of administration of the Company's business and makes a contribution to the remuneration of the directors and to the maintenance of the value of the Company's Pension Fund so that it may be adequate to meet all subsisting and future liabilities. The Direct Co. retains its reserve fund (£512,323. 2s. 11d.) and remains responsible for the repair and renewal of the leased properties. Provision is made that the Direct Co. shall not be at liberty to pay a dividend of over

Digitized by Google

5 per cent. per annum without the consent of the Western Union Co.

All these matters will be fully put before the shareholders at the meeting of both companies at Winchester House, London, on Friday next, Sept. 29.

Mention has been freely made of late of the Sherman Anti-Trust Act and its effect upon the relations between the cable and telegraph companies for the British and American services, and this mention of the Anti-Trust Act has led to much correspondence in the American journals. Among the statements published on this and other points which have been raised is a lengthy one from Mr. George Clapperton, the well-known vice-president of the Commercial Cable Co., from which we make the extract following :—

The announcement (of the Western Union Co.) is grossly erroneous in its statement that cables are utilised to the extent of only about 25 per cent. of their capacity. By working continuously day and night the cables might carry a third more matter than they do carry, but this does not allow for cables out of service because of injury, or unfavourable electrical conditions, or the interruption of terminal land lines. The cable service must be apportioned like any other service which has to deal with congested periods. Its facilities must be expensive enough to take care of its customers during the busy hours. The announcement does not disclose the essential feature of the transaction, and is made for the purpose of covering up the march of the vast Telephone-Telegraph-Cable combination to an illegal monopoly.

In the last report of the American Telephone and Telegraph Company the stand was boldly taken that the cost of aggressive uncontrolled competition was eventually borne by the public and should be eliminated. It will be borne in mind that that company formerly gave a night message rate on its long distance telephone lines, but after it had fully established itself it abolished these night message rates. That is what will happen in the telegraph and cable business if the combination ever succeeds in establishing a monopoly. The plan is not for the public good.

There is very good reason for the Western Union trying to cover up these transactions by talking about reducing cable rates away back in 1882. Those three companies formed a pooling agreement by which they divided, in fixed proportions, their entire Atlantic cable receipts. That pooling agreement was lived up to by all three of those companies until March, 1911; then the Western Union suddenly notifies the Anglo-American and Direct United States Cable Companies that that pooling agreement was in violation of the Anti-Trust Act of Congress of July 2nd, 1890. You will notice that for 21 years, namely from 1890 (the date when the Anti-Trust Act was passed) to 1911, down to the present year, the burning coal of illegality has been lying upon the tortoise back of the Western Union conscience. It quickened when the Western Union coveted the property of its two allies and friends. Accordingly the Western Union on March 1, 1911, threw out the Anglo-American and Direct from the eastbound Atlantic cable business which the Western Union collected by its telegraph system throughout the United States, and which the Anglo and Direct Companies could not collect because they had no American land line telegraph system of their own. That action by the Western Union on March 1, 1911, was for the purpose of clubbing the two English companies into leasing their cables to the Western Union, and it accomplished that purpose.

The pertinent question now is how can this combination by lease be legal, if the combination by pool was illegal? If the Anti-Trust Act of Congress prohibited one how in the world does it not prohibit the other? If it is illegal to combine by pool, it is equally illegal to combine by a lease, and in fact it would seem much more so, because the lease is to cover 99 years, and gives control of the physical properties instead of merely dividing receipts.

This utter disregard of the law and public sentiment in regard to combinations beats anything I have seen lately. It remains to be seen what the attorney-general of the United States will do about it. The proof of the attorney-general is absolute, inasmuch as the notice of the Western Union to the Anglo and Direct Companies that the pooling agreement was illegal under the Anti-Trust Act of Congress is an admission that that Act of Congress prohibits the combination of those three cable companies in any form. Even the counsel of the combine has advised that it is impossible in the present state of decisions to pronounce with certainty upon the validity of the agreement. I get this from the notices which were issued yesterday to the stockholders of the Anglo-American and Direct Companies.

One thing is certain, and that is that the outrageous inconsistency of the whole proceeding on the part of the Western Union has not helped the standing of American business methods in London. So far as a reduction of cable rates is concerned, a reduction was arranged a long time ago with all the cable companies and will be put into effect as soon as the Postmaster-General of Great Britain can bring some other Governments into line.

STOCK EXCHANGE NOTICES.—The Stock Exchange Committee have granted quotations to £441,620 5 per cent. first mortgage convertible bonds of the *Cuban Telephone Co.*; 268,235 10s. fully paid ordinary shares, and 80,000 £1 fully paid 6 per cent. cumulative preference shares of the *Hastings and District Electric Tramways Co.*; 20,000 £5 fully paid 7 per cent. first cumulative preference shares of the *Melbourne Electric Supply Co.*, and a further issue of £400,000 5 per cent. 50 year mortgage bonds of the *Rio de Janeiro Tramway, Light and Power Co.* The Committee have been asked to grant a quotation to a further issue of 40,370 £5 fully paid 5 per cent. cumulative preference shares of the *Calcutta Electric Supply Corpn.*

PATENT RECORD.

APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned Applications (except those marked †) are not open to public inspection until after acceptance of Complete Specifications. Those marked* are open for inspection 12 months after the date attached to them, if they have not been published previously in the ordinary course. Names within parentheses are those of communicators of inventions. When complete Specification accompanies application, an asterisk is affixed.*

August 2, 1911.

17,550 BRODIE-INNES. (Ela Archer, U.S.) Life-saving belt for electricians.
17,567 BURTON. Electrically-controlled clocks and the like.
17,587 GWOZDZ. Thermic telephones. (Addition to 11,234/11. Convention date, 22/4/11, Germany.)*
17,593 ANNESS. Electrical terminals.
17,595 GWOZDZ. Telephones. (Addition to 11,234/11. Convention date, 22/4/11, Germany.)*
17,597 FELTEN & GUILLEAUME CARLSWERK AKT.-GES. Treating substances by electro-osmosis. (Convention date, 2/8/10, Germany.)*
17,605 ASHCROFT. Electrolytic manufacture of metallic sodium and potassium and electrolyte for use therein.
17,612 OLDHAM. Terminals for electric storage batteries or other purposes.*

August 3, 1911.

17,634 KRAMER. Inductive wireless telephone and telegraphic installations.
17,635 DODDRELL. Method for timing telephone calls.
17,675 Pieper. Speed regulation of dynamo-electric machinery. (Convention date 6/8/10, Germany.)*
17,678 PEMBERTON. Apparatus for the destruction of flies and other insects by electricity.
17,685 STILL & SONS, ADAMSON & KITSON. Incandescent lamps.
17,690 SCHIFF. Carbon electrodes.*
17,708 BALCOMBE & CALVERLEY. Regulating device for electric generators or motors.
17,716 COOPER. Electric motors and dynamos.
17,718 ZENNER. Time switches and the like.*
17,723 B.T.-H. Co. (G.E. Co., U.S.) Arc lamp electrodes.*
17,724 B.T.-H. Co. (C.E. Co., U.S.) Electric switches.

August 4, 1911.

17,761 FIELD. System of electrical cab signalling for railways or the like.
17,768 SIEMENS-SCHUCKERTWERKE G.M.B.H. Driving of rotary field induction motors. (Convention date, 4/8/10, Germany.)*
17,778 WETTER. (Ges. fur Maschinen und Metall-Industrie m.b.H., Germany.) Electric arc lamps.
17,780 B.T.-H. Co. (G.E. Co., U.S.) Method and apparatus for shaping filaments for electric incandescent lamps and the like.
17,784 EDMUNDS. Device for reducing the electrical disturbances produced in electrical signalling circuits by the proximity of alternating currents.
17,788 ALLISON & ARNOLD. Electric switches for use with timing or other predetermining mechanism.
17,791 LEITNER. Means for regulating electric lamp circuits.
17,810 WELCH & FROST & Co. Electrical heating apparatus, particularly vulcanisers.
17,820 GWOZDZ. Telephones. (Addition to 11,234/11. Convention date, 22/4/11, Germany.)*

August 5, 1911.

17,835 GREENWOOD. Dynamo-electric machines.
17,840 DOWDELL. Arc lamps.
17,869 SIEMENS BROS. DYNAMO WORKS. (Siemens-Schuckertwerke G.m.b.H., Germany. Holders for electric lamps.*
17,874 WESTERN ELECTRIC CO. (Western Electric Co., U.S.) Registering device for telephone systems.*
17,875 WESTERN ELECTRIC CO. (Western Electric Co., U.S.) Telephone receivers.*
17,900 GWOZDZ. Telephones. (Addition to 11,234/11. Convention date, 22/4/11, Germany.)*

August 8, 1911.

17,932 DOUGLAS. Design applicable to magneto cut-out and control.
17,978 SCHEPELER. Receiving apparatus for electric transmission of signals. (Convention date, 5/8/10, Germany.)*

August 9, 1911.

18,036 STAFFORD & BARNES. Carriers for supporting incandescent lamp shades.*
18,051 KLEINSCHMIDT. Electric power transmission devices.*
18,078 MEIROWSKY & Co. A.-G. Insulation material. (Convention date, 18/4/11, Germany.)*
18,080 GWOZDZ. Telephones. (Addition to 11,234/11. Convention date, 26/4/11, Germany.)*
18,082 BOSCH. Starting combustion motors having magneto ignition. (Convention date, 1/10/10, Germany.)*
18,083 BOSCH. Interrupter for the electric ignition of internal combustion engines. (Convention date, 10/4/11, Germany.)*

August 10, 1911.

18,115 TAYLER. Automatic switch for telephone circuits.
18,131 HANDCOCK. Wiring of installations.
18,132 LAMME. Windings for dynamo-electric machines. (Convention date, 6/9/10, U.S.)*
18,160 GRIGSBY. Reflector fittings for electric lamps.*

SPECIFICATIONS PUBLISHED.

1911 SPECIFICATIONS.

8,283 CROOK. Selective electric signalling over a number of conductors.
8,387 GOLDSCHMIDT. Method of and means for receiving electric waves in wireless telegraphy and telephony. (4/4/10.)
8,783 LEWIS. Control systems for alternating-current electric motors. (9/4/10.)
8,890 HATHORN, DAVEY & Co. & TOWLER. Controlling gear for or connected with electrically-driven hydraulic pumps.
8,901 STASJANO. Electric furnace.
9,038 CRESWICK & BENTHAM. Cartridge fuses for electrical purposes.
9,050 LOBEL & BRITISH EVER READY ELECTRICAL CO. Portable electric lamps.
9,201 RAILING & BARTLETT. Cooling of the commutators of dynamo-electric machines.
9,633 IMRAY. (Shawinigan Carbide Co.) Electrodes for electric furnaces.
10,080 CHAMBERLAIN & HOOKHAM (LTD.). & HOLDEN. Electricity meters.
10,341 SIEMENS BROS. & CO. (Siemens & Halske Akt.-Ges.) Subscribers' instruments for automatic telephones.
10,545 ZICKEL. Electric shutter indicators. (2/5/10. Addition to 26,502/08.)
10,639 GALLETTI. Production of quenched electrical spark discharges. 3/5/10.)
10,767 FROSALI & VISCONTI. Electrical heating apparatus.
10,834 SIEMENS BROS. & CO. (Siemens & Halske Akt.-Ges.) Alternating current block circuits for railway signalling.
12,117 SIEMENS BROS. & CO. (Siemens & Halske Akt.-Ges.) Semi-automatic telephone exchange systems.
12,742 WHALTON. Electric hammers. (26/5/10.)
12,921 ALLGEMEINE ELEKTRICITATS-GES. Systems of electric motor control. (27/5/10.)
13,707 SIEMENS BROS. & CO. (Siemens & Halske Akt.-Ges.) Electrical measuring instruments of the dynamometer type.
13,317 SOCIETE ANONYME ELECTROMETALLURGIQUE. (Procédés Paul Girod.) Method of supplying electric furnaces with triphase currents. (9/6/10.)
13,715 SUCHTING & OLOFF. Thermo-electric batteries.
13,808 RODECK. Electro-deposition of metals. (10/6/10.)
13,985 ALLGEMEINE ELEKTRICITATS-GES. Railway signals. (10/6/10.)
14,432 SIEMENS-SCHUCKERTWERKE GES. Automatic regulators for electric circuits. (17/6/10.)
17,047 GES. FUR CHEMISCHE INDUSTRIE IN BASEL. Apparatus for the electrolysis of fused alkali chlorides. (22/12/09.) (Divided application on 18,300/10, Aug. 2.)

COMMERCIAL AND INDUSTRIAL SECTION.

MUNICIPAL, FOREIGN & GENERAL NOTES.

BRITISH NOTES.

Aberdeen.—The Electricity Committee recently fixed the rate for electricity for lighting at 3½d. per unit, 2½d. to ⅝d. for power, and 1d. for heating. The reduction in the charge for lighting is ¼d. per unit.

Bacup.—Sanction to a loan of £1,250 for electricity supply has been applied for by the Council.

Bath.—An inquiry was held here last week into the Council's application for sanction to borrow £7,900 for additional electric generating plant.

It was stated that the money was required for a Diesel oil engine and electric generator, motor alternator and coaster, &c. In the course of the inquiry the electrical engineer (Mr. F. Teague) asked the inspector to make the amount a round £8,000 so as to provide for contingencies.

Replying to the inspector (Mr. T. C. Ekin), Mr. Teague gave particulars of the proposed plant. Unfortunately they had been unable to obtain an English-made Diesel of the size they required, and they had been obliged to get one made by Carels Frères, of Ghent. That firm had built engines of the size they required. They proposed to put in a three-cylinder engine about 250-260 H.P. per cylinder. The total cost would be £5,451, the Diesel Company being responsible for the whole combination. The storage tank would be made through a local tender, and price would be based on that of previous tanks. It was for the foundations that he wanted the contingency money. The booster would cost £400, and it was required to enable them to supply Messrs. Stother & Pitt, who were their largest consumers for power. The cost for the steam driven plant for the year to March 31, for 1,750,000 units was £5,625. That included wages, waste, maintenance and everything connected with generation, but excluded distribution. He estimated that the Diesel engine would generate 1,000,000 units per year, and would run for 80 per cent. of the total number of hours in the year. The dimensions of the full tank was 15 ft. × 10 × 10, and was sufficient for one week's supply. That was considered sufficient, as at Avonmouth (20 miles away), where they got their oil supply, there was always an available supply of 6,000,000 gallons of oil there. In case of a railway strike it could be brought to Bath by road or river.

Bermondsey (London).—The Electricity Committee report the loss of about 75,000 units owing to many consumers shutting down their works in consequence of the late strike. The figures for the current month would also be affected, and there would be a serious loss of revenue.

Bexley.—Last week the Council adopted a scheme for the wiring of consumers' premises on the deferred payment system.

Carlisle.—An unopposed inquiry was held on Tuesday into the application of the Corporation for sanction to borrow £9,000 for mains extensions, the provision of a new storage battery, &c.

The Town Clerk gave particulars of the ratable value, existing loans, &c., and the borough electrical engineer (Mr. S. T. Allen) said that six tenders had been received for the new battery, and the lowest, which was accepted, amounted to £1,755. With regard to the adaptation of the Unitarian Church to the purposes of the Electricity Works, it was stated that £2,750 was the actual purchase money paid for the church, and the adaptation of the building would cost £369. Among other things there would be a new office provided, leaving the old office to be used for stores.

Carnarvon.—On Wednesday the Council decided to adopt electric lighting for the central portion of the town at an estimated cost of £100 per annum.

Douglas (Isle of Man).—The Council have retained Messrs. Handcock & Dykes to report on the proposal to establish electricity works and to construct municipal electric tramways.

Dublin.—The Port and Docks Board have agreed to allow the city electrical engineer (Mr. M. Ruddle) to lay electric mains across O'Connell Bridge.

Electric Fan for Queen Mary.—The American General Electric Co., at their Pittsfield works (Massachusetts), have just made an electric fan for Queen Mary of England. The fan is mounted in gold and has an ebony switch. It has been specially designed en suite with the Royal toilet articles, and is a present from some of the Queen's American admirers.

Electrically-operated Transport Scheme.—Mr. A. W. Gattie continues to move ahead with his great scheme for the transport of goods from a central source, where they will be put on trains by electrically-operated unloading and loading machinery. His great scheme, which has been fully explained in our columns, is certainly making progress, and Mr. Gattie's activities in this direction promise to be fruitful at no distant date. Many men of light and leading are beginning to take an interest, financially and otherwise, in the project, and the leading newspapers are giving their readers up-to-date particulars of the progress that is being made. A recent contribution on the subject appeared in the "Standard" (London) on Sept. 14.

Electricity in Mining.—The Cramlington Colliery Co. are erecting an electricity generating station at Cramlington colliery, at a cost of £10,000.

Exhibition Awards.—Mr. R. Wolf, 7, Laurence Pountney Hill, London, E.C., and Magdeburg-Buckau, who secured a number of distinctions last year at the Brussels and Buenos Ayres Exhibitions (3 grands prix), has now been awarded a grand prix for "Wolf" superheated steam locomobiles shown at the exhibition of the North of France at Roubaix, and the firm has also received the gold medal of the Imperial Russian Ministry of Industry at Odessa. These honours complete a series of highest awards obtained by "Wolf" locomobiles this year at the exhibitions at Omsk, Siberia (2 gold medals), Crefeld (Germany) and Allahabad, India (gold medals).

Hammersmith (London).—In Nov., 1907, the Council agreed to supply Messrs. Gwynnes (Ltd.) with one 50 H.P., four 30 H.P., one 18 H.P and three 10 H.P. motors in addition to a spare motor and a motor generator upon hire, subject to the company entering into an agreement to take current for five years. As the firm now desire three additional motors on similar conditions the Electricity Committee have decided to purchase the motors required and lend same to the company provided they take current for a further period of five years on the terms of their present agreement.

Ilford.—In a report on the tramways undertaking for the past year it is stated that, although a considerable amount had been spent in equipment, a balance out of revenue of £679 was being carried forward, which with interest (£778) made a total of £6,919. The surveyor has been instructed to put in a crossover at the Loxford Bridge terminus at a cost of £130.

Light Railways.—Application is being made to the Light Railway Commissioners for an order authorising a lateral and vertical deviation from the lines shown on the original plans of the Gosport & Lee Light Railways.

Mansfield.—The Council have received sanction to a loan of £3,500 for the electricity undertaking.

Marylebone (London).—The Electrical Contractors' Association have threatened to bring an action against the Borough Council to restrain them from carrying on their wiring and fittings department.

At the Council meeting on Oct. 5 Councillor O. Lewis will move that this Council does not desire to continue competitive trading and that the Electric Supply Committee be instructed to report to the Council as to the advisability of discontinuing the execution of contracts for wiring and the sale of electric fittings.

Norwich.—On Tuesday the Council decided that, as there was no possibility of an arrangement being come to for the purchase of the undertaking of the Norwich Electric Tramways Co., there was no use in entering into negotiations for their acquisition.

Presentations.—Presentations have been made to four members of the staff of the Aberdeen electricity works who are leaving for situations in Vancouver and Australia. To Messrs. A. Allan and A. Rowell a kit bag each, to Mr. Pirie a Gladstone bag and to Mr. J. Coutts a watch were presented.

The staff of Siemens Bros. Dynamo Works (Stafford) have presented a silver tea service to Dr. M. Kloss, who is leaving to take up a university professorship in Germany.

Radcliffe (Lancs.).—The Lancashire Electric Power Co. have decided to renew their application for a provisional order to enable them to supply electric energy for power in this district.

In 1910 the company's application for a provisional order was refused by the Board of Trade, as there was a municipal electricity supply scheme in operation. In communicating their decision the Board stated that "the facilities afforded to power users in Radcliffe to obtain a supply of energy at reasonable terms were inadequate, and in the opinion of the Board should be promptly extended by varying the arrangement with the company or otherwise; and in the event of the company making a fresh application at some future date, and it being shown that the demand for energy for power purposes is not being adequately met, the Board may find it necessary to arrive at a different conclusion." In September, 1910, representatives of the company (Messrs. F. E. Gripper and C. D.

Digitized by Google

Taite) had an interview with Mr. E. M. Lacey, consulting engineer of the Council, and in consequence of this interview the company's proposals for arriving at a settlement were put into writing, and included the following suggestions:—

1. That applications from power users be divided into two classes, namely, (*a*) those coming from power users who desire a supply of energy for use within a certain radius of the Council's generating station, and (*b*) those coming from power users desiring a supply outside the said radius.

2. That all applications from power users within the radius be referred to the Council to supply if they so desire. If the Council is unable to give the supply the application shall be referred to the company, and if the company is successful in arranging for a supply to be given, the company shall be empowered by the Council to give the supply for a term of years; and if at the end of the term the Council is desirous of taking over the supply, the Council shall purchase the service cables on terms to be agreed. If the Council do not desire to take over the supply, the agreement empowering the company to give the supply to be renewed.

3. That the company be given general powers to deal with all enquiries received from power users outside the said radius provided that the supply required is equivalent to 50 H.P. or upwards. If the power user requires less than 50 H.P. the inquiry to be dealt with as provided under proposal 2.

4. That the company notify the Council when any agreement to give a supply has been entered into under the above proposals, and that the company pay the Council an annual acknowledgment in each case, the amount of such acknowledgment not to exceed one guinea per annum.

The company's offer appears to have been ignored, but on Jan. 31, 1911, the Council invited the company to quote for supply of electricity in bulk, in accordance with certain requirements, and in due course a quotation was submitted. Correspondence followed, and eventually the company, in the hope of coming to terms, made a reduction in the price originally quoted. Ultimately the Council decided to take a supply of electricity from Bury Corporation. Mr. Taite contends that his company has not been fairly treated, and maintains that if any preferential treatment is to be granted, the power company should be the favoured party rather than Bury Corporation. He sets out his reasons for this in the "Bury Guardian" of the 16th inst. It is submitted that if an agreement is made with the power company so that the company can supply large users of power direct and the Council the smaller consumers, the district will benefit in various ways, and that Radcliffe Council, if they decide to buy power from Bury rather than from the power company, will be lending themselves to forging another link in the chain in favour of Radcliffe's ultimate absorption by Bury. In conclusion, Mr. Taite states that "the company has no desire to in any way infringe the Council's privileges; but being convinced as we are on the one hand of the potential demand for electrical energy from Radcliffe power users and from manufacturers who could be brought into the district were the attitude of the Radcliffe Council more encouraging, and being faced on the other hand with the determined hostility of the Council, the company is bound to assert itself."

St. Pancras (London).—The Finance Committee will utilise £6,977 of the £13,203 profit on the electricity undertaking for the past year in relief of rates. The Electric Lighting Committee will continue the central arc lighting in the widened portion of Euston-road.

Southampton.—Extensions of the tramcar depot at Portswood are to be carried out at an estimated cost of £3,400.

Sunderland.—The Health Committee have accepted the offer of the Lighting Committee to supply electric current for the lighting of each tenement in the Harrison Buildings at 4d. per week.

Walsall.—The Electricity Committee have placed on record their satisfaction at the ability and energy displayed by Mr. Ashton Bremner during the period of six months for which he has been acting electrical engineer of the Corporation electricity undertaking, and the manner in which he has discharged, under trying circumstances, the numerous duties devolving upon him during the absence (owing to illness) of the Borough electrical engineer (Mr. A. S. Barnard), and they have instructed that a copy of the resolution under the common seal should be forwarded to Mr. Bremner.

Wireless Telegraph Notes.—Successful wireless communication was established last week between the French military air cruiser "Adjudant Vincennott," at Lamotte-Breuil and the fortress at Verdun and the Eiffel Tower in Paris, during the whole of a 13½ hours' flight.

The wireless installation at the General Post Office (London) is reported to be nearing completion. On the roof of the south block at the G.P.O. the masts of the installation may now be seen. The equipment is not intended to be used for public messages, but it will be devoted to the carrying out of tests by the engineering staff.

The action brought by the editor of the "Los Angeles Herald" against the editor of a rival journal for intercepting by amateur wireless operators a message sent to the former has been decided. The court held that no offence was committed by the amateurs in intercepting the message or by the rival paper in publishing the intercepted message. The ruling is regarded as unsatisfactory in wireless quarters, and it is probable some further steps may follow to have the decision reversed.

COLONIAL AND FOREIGN NOTES.

Argentina.—A 30-years' concession has been granted to Senor Antonio Grego for the installation and working of a telephone system at Macachin, in the Pampa Central district.

Australasia.—In consequence of the enormous increase in railway traffic, 48 acres of land have been purchased in connection with improvements at the Rome-street station (Brisbane), and on this land it is proposed to construct engine and carriage cleaning sheds, coal stages, and an electric generating station, with sufficient plant to drive all the machinery in and to light the several buildings, and all the suburban stations and tunnels.

The half-yearly report of the Electric Light & Power Supply Corpn. (Balmain, N.S.W.) states that there were 299 consumers in Balmain and 178 in Newtown. The company has entered into an agreement with Petersham Council for the supply of electric light and power in Petersham. A dividend at the rate of 5 per cent. has been declared.

"The Australian Mining Standard" states that for the year ended June 30, 1910, about 187,000,000 passengers were carried by the N.S.W. tramway department, Sydney, and up to June 30 this year the total was 230,000,000. Revenue last year was £1,090,000. At present all the electric power for the service is obtained from the Ultimo power house. On special occasions the output has been hardly sufficient, and it has been decided to erect a new station at Rozelle, in the western suburbs. The proposed plant will, it is stated, be the largest and finest in Australia and will comprise ten 5,000 kw. turbo-alternators. Tenders for the first five turbo-alternators are due by Oct. 30 next.

The Wages Board which decided, amongst other matters, in June, 1910, that linesmen's and arc-lamp trimmers' wages shall be 8s. 6d. per day has been asked by the Secretary of the Electrical Trades Board of N.S.W. to vary the award by increasing this minimum. Mr. Black says Sydney Council pay linesmen 10s.

A new wing has been added to Sydney Technical College, the lower storey of which will be devoted to electrical engineering. New plant for electrical students is to be obtained. There are over 2,500 students attending the college.

During the first wek of August an Order-in-Council was issued authorising the municipalities of Prahran, St. Kilda, Malvern and Caulfield to construct an electric railway between Caulfield, Prahran and St. Kilda. The contractors for the construction of the line (Messrs. Youlden & Howitt) had commenced the construction work, when the men (80 in number) "struck" for an additional 1s. a day.

Woodonga (Victoria) Electric Supply Propy. (Ltd.) has been formed to take over an electric supply concession from Woodonga Shire Council.

The question of the allocation of the cost of regrading the South Geelong (Victoria) Railway to allow the proposed Belmont tramway to run under it has been settled. The Melbourne Electric Supply Co. and the Geelong Council will pay £2,000 each and the Railway Commissioners the remaining £11,000.

Bairnsdale (V.) Shire Council will shortly consider a proposal to borrow £5,000 for electric-lighting plant.

The demands made on the electric power plant at Korumburra (V.) by Poowong and Jeetho Council have increased so rapidly that it is proposed to secure a larger battery.

Renewed attention is being given in the Bendigo district of Victoria to the question of the supply of electricity for haulage and other purposes at the various mines. Mr. G. Smith Morison (Melbourne manager for Siemens Bros. Dynamo Works), Mr. Walter Tuerk (electrical engineer), and Mr. Hoffman (geological expert of the Prussian Government) recently visited Bendigo and inspected various mines. It is reported that the visitors obtained the impression that the Bendigo field was most suitable for the application of electric power.

At a recent meeting of Sydney Electric Light Committee, the city electrical engineer (Mr. H. R. Forbes-Mackay) suggested that a duplicate of the two 4,000 kw. sets, recently installed at the Council's station, be ordered from Messrs. Dick, Kerr & Co. at a cost of £17,245.

Corowa (N.S.W.) Council have adopted a scheme (prepared by Mr. G. A. Julius) for the erection of a small generating station of about 50 kw., the generator being driven by a gas or Diesel oil engine.

The negotiations for the formation of a company to take over the patents, &c., of Complex Ores, Ltd., have been practically completed, and a contract for underwriting the capital has been entered into. The contract stipulates for the immediate provision of the capital necessary for carrying on the hydro-electric part of the scheme, also for a supply of capital as required for other enterprises of the company. The new company is to be known as Hydro-Electric and Metals (Ltd.) and arrangements have been made for the underwriting of £145,000 5 per cent. debentures. The Great Lake hydro-electric works, Tasmania, have been in progress for a considerable time. It is proposed to generate 9,000 H.P. out of which 2,500 H.P. will be required in Hobart. The canals and pipes leading to the power house are to be large enough to give 40,000 H.P., and the first power main to Hobart will be able to transmit 15,000 kw. The company has carbide patents and has also secured the Australian rights for an iron and steel electric furnace. These industries, with the metallurgical works for utilising the J. H. Gillies electrical process for the deposition of zinc, are to be started simultaneously at North West Bay, 10 miles from Hobart.

Canada.—The General Assembly of Nova Scotia recently passed an Act by which the Government can grant aid, under certain con-

Digitized by Google

ditions, to companies proposing to construct electric railways in the province. This aid may take the form of a subsidy not exceeding £410 per mile, a loan not exceeding £1,640 per mile of railway built and worked, or a guarantee of the bonds or debentures issued.

The Dominion Government will grant assistance towards the construction of the proposed civic hydro-electric works at La Colle Falls, on the Saskatchewan River. Mr. Cecil B. Smith, who supervised the construction of the Winnipeg power plant, thinks that the new power plant in Prince Albert will result in largely increased activity in manufacturing in the city.

China.—A Shanghai journal states that the Peking Board of Communications has authorised an inquiry into a tramway scheme for Peking.

Colombia.—The municipal authorities of Riosucio have consented to a proposal by Mr. Geo. Gartner to erect electricity works for the town.

Electric Traction in Chili.—It is reported that the Chilian Government does not propose to accept any of the tenders submitted for the electrification of the Santiago-Valparaiso section of the State railways, and that it will carry out the work itself. The cost of the operation, according to the Westinghouse Co.'s tender, will be about £4,500,000.

Germany.—The report of the British Consul-General, Sir F. Oppenheimer, on the trade of Germany for 1910 and the first four months of 1911 states that the import of copper in 1910 was 181,551 tons (compared with 154,672 tons in 1909) and that this increase may be regarded more especially as a criterion of the activity in the German electrical industry, which consumes nearly half of the 200,000 tons of copper annually imported into Germany.

A Bill is being promoted to revise the rates for telephones so that the annual subscription will entitle the subscriber only to a limited use, all calls beyond a given number being paid for on the message-rate system. Among the industries for which the year 1910 was above the ordinary were the electrical, the chemical and the toy industries; the machinery industry also fared better than during recent years. In the electrical and chemical industries, and to a certain extent also the machine industry, the steady rise is due to the scientific training as applied to industry which has ensured a stock of highly skilled workers. The electrical industry had barely been affected by the last commercial depression. It steadily conquers new fields (shipbuilding, mining, the production of steel, &c.), and when a revival of trade sets in it benefits from an increased demand in its new branches also. In Germany the industry is combined in three large concerns. These firms compete against each other for the erection of electric power transmission works, which have of late increased with exceptional rapidity. They erect power stations for parish or rural councils, and endeavour as far as possible to manufacture in their own workshops and factories all the material which is necessary for such stations. On the other hand there also exist in Germany electrotechnical factories, which specialise in the manufacture of the extraordinarily numerous electrotechnical products. These employ 55,000 hands out of a total of 125,000 engaged in the industry. There is a third group (the electrical installation firms), but the first-named concerns have tried by means of ingenious contracts with communities and district councils to exclude more and more the competition of the other two branches and so to secure for themselves the furnishing of the entire material and the installation work. Most of the Governments which make up the German Empire have prohibited the conclusion of such contracts, and have warned the communities against allowing any creation of private monopolies. Among all German industries (continues the report) there is none which so thoroughly resembles the much-dreaded American Trust in aspect and methods as the electrical industry. The export of motors and dynamos amounted to 299,687 doppelcentners (the doppelcentner is equal to 220 lb.) in 1910 against 237,380 doppelcentners in 1909. Of electric lamps there were exported 19,782 doppelcentners against 16,552; arc lamps, 7,491 against 7,601; electrical appliances for lighting, transmission of power, &c., 99,563 against 71,895; and telegraphic apparatus, &c., 15,708 against 16,004 in 1909. The value of the export in these six groups alone amounted in 1910 to 146,000,000 marks against 116,000,000 marks in 1909.

The Prussian State Railway administration seems inclined to introduce electric power. In 1909 the means for the necessary experiments on a full gauge line were voted by the Landtag. The line chosen was the one between Bitterfeld and Dessau, 26 kiloms. (over 16 miles) in length, which forms a part of the Magdeburg Leipzig Halle main line. The electrification was begun on Jan. 18, 1910, and the line was in working order at the end of the year. Electric power was produced in a generating station in the centre of that lignite district. The State has secured the supply of brown coal at 2 marks per ton for 30 years. The results achieved with this experimental electric railway are described as extremely satisfactory. Speeds of 125 kiloms. per hour were reached, the working itself was characterised by punctuality and cleanliness, the permanent way is spared wear and tear, and the work of the staff is facilitated. A memorandum presented to the Prussian House of Representatives states that the experiments with electric locomotives on the line have been so satisfactory that the Prussian State Railway Administration will in future pay the greatest attention to electric traction for trains, the more so since steam locomotives have reached a degree of perfection which would almost seem to exclude any further improvement. In spite of the excellent work done by steam locomotives they will in future not be able to meet the increased demands of the passenger and goods traffics. The size of the new express locomotives cannot be exceeded for technical reasons, and owing to their enormous consumption of coal the firing of these giant machines by hand is already causing serious difficulties. It will in future be necessary to fall back upon electric locomotives if the speeds and the number of trains are to be increased. The advantages of electric over steam traction are very considerable, and include diminution of working expenses in consequence of concentration of power production, the use of lignite instead of mineral coal, the diminution of the dead weight of trains through the absence of fuel and water, the greater power of electric locomotives, which can under certain conditions accomplish non-stop runs of many hundred kilometres, decreased cost of maintaining locomotives and permanent way, the possibility of heavier traffic through an increase in the number of trains, the absence of damage done to adjoining land by sparks from the engine, increased facilities for the men no longer exposed to the weather and to coal dust since the driver's cabin in an electric locomotive is entirely closed and in view of the simplicity of the working of an electric locomotive, the driver can pay even greater attention to signals.

Italy.—The Soc. Italiana di Industrie Elettriche, Spezia, have obtained a concession for the construction of an electric tramway from Spezia to Cadimare.

Poland.—A consular report on Poland and Grodno says there is a good opening in the Lodz district for steam turbines and electrical machinery. Important orders for this class of machinery are constantly being placed in Germany. By far the greater number of steam, gas and oil engines continue to be imported from Germany and Austria. It is seldom that an English made steam engine is heard of in this district, and the question of price, it is asserted, is not the cause for this.

Buildings of from 8 to 14 storeys are being built in this district, and there is a good opening for lifts of British make. The trade is at present in German and American hands. Electric lifts find most favour.

Electric light is practically always installed in the new buildings, either alone or in conjunction with gas. Birmingham electroliers and electric light accessories are both cheaper and better than the German goods, but British manufacturers of these articles are little represented in Poland.

ELECTRICITY SUPPLY AND TRAMWAY ACCOUNTS.

Ayr.—The report of the borough electrical engineer (Mr. R. Marshall) for the year ended May 15 states that the capital expenditure is £103,367, increase £1,038 over 1910.

Income was £14,851 (decrease £16), working and general expenses were £6,868 (increase £115), gross profit was £7,983 (decrease £131), and net profit £2,256 (decrease £188). Total (equivalent) 30 watt lamps connected are 72,470 (increase 4,220), including 138 motors (500 H.P.). There are 109 arc and 242 incandescent lamps for public lighting, and all the latter have been converted from 32 c.p. carbon to 64 c.p. metallic filament lamps, not only doubling the candle power, but considerably reducing the consumption for pulic lighting by 52,052 units. The total units sold were 1,456,394 (decrease 26,089).

The total revenue of the tramways department for the year ended May 11 was £15,492, an increase of £485. The number of passengers carried was 3,760,746, an increase of 82,118, and the car-miles run was 386,434, a decrease of 1,270, due chiefly to a reduction of the service during the winter months. Working expenses (excluding power) amounted to £6,429, or 3·99d. per car mile, and including power charges to £8,492, or 5·29d. per car mile. The percentage of working expenses to receipts was 54. Revenue from parcels delivery again showed satisfactory increase. The number of parcels dealt with was 22,046, and the receipts amounted to £148. The balance from the year's working was £3,046, of which £1,963 was carried to depreciation and renewals fund and £1,083 was transferred to the Burgh general assessment.

Newcastle-on-Tyne.—The accounts of the Corporation tramways department for the year ended March last show capital expenditure (including public lighting) £1,184,644 and the total amount of loans repaid and sinking fund instalments is £301,189.

Revenue was £215,850 (£209,676 in previous year), gross profit was £101,877 (£92,081) and, after meeting capital charges and contributing £1,538 to rates (for interest, &c., on unexpired horse tramway loans) the surplus was £23,703 (£15,120). 45,335,207 (44,516,958) passengers were carried, 4,437,639 (4,430,085) car-miles run and 8,481,806 (8,213,651) units used. Traffic revenue per car-mile was 11·15d. (11·016d.) and total operating cost was 6·164d. (6.37d.)

Portsmouth.—The accounts of the electricity supply department for the year ended March show capital expenditure £339,083 (increase £4,266).

Revenue was £47,309 (against £47,194), working and general expenses were £21,845 (£24,321), gross profit was £25,464 (£22,873). After meeting capital charges and paying £367 income tax, the balance was £4,579 (£1,801), of which £579 (£301) has been transferred to insurance fund, £3,500 (£1,500) voted in aid of rates and £500 carried forward. Units generated were 45,38,500 and units sold 3,464,420. Total maximum supply demanded was 2,720 kw. Public lamps include 272 large and 144 flame arcs and 496 incandescents.

At the last meeting of the Electric Light Committee Coun. Mactavish criticised the policy of applying the profit to relief of rates. The method

Digitized by Google

of using the profits from the undertakings must necessarily mean discriminating between one class of ratepayers and another. A small amount of the profit might be used for the relief of rates, but the bulk of it should be used for extension of the system, increasing wages, &c. The trading committees of the Council paid too much (£15,000) to relief of rates.

Coun. H. R. Pink, who supported the proposal, said that while ratepayers benefited from profits, they had also to meet the losses on some undertakings, and after some discussion the report was adopted.

TRADE NOTES AND NOTICES.

TENDERS INVITED.

Tenders are invited up to Dec. 20 for the supply of one branching multiple magneto switchboard at Broken Hill to the Postmaster-General's Department in NEW SOUTH WALES. Tender forms and specification from the Commonwealth Offices, 72, Victoria-street, London, S.W. See an advertisement.

Tenders are invited up to Nov. 21 for supply of one automatic or semi-automatic switchboard and equipment to the Postmaster-General's Department in WESTERN AUSTRALIA. Tender forms and specifications may be obtained at the Commonwealth Offices, 72, Victoria-street, London, S.W. See an advertisement.

Tenders are invited up to Nov. 1 for the supply of 5,000 porcelain (No. 8) insulators to the Postmaster-General's Department in SOUTH AUSTRALIA. Tender forms and specification from the Commonwealth Offices, 72, Victoria-street, London, S.W. See an advertisement.

Tenders are invited by the City of MELBOURNE for the supply of 8,000 yds. three-inch fibre conduit, suitable for laying underground in concrete, and to be used for containing lead-covered cables. Specifications, &c., from the Agents for the City Council, Messrs. McIlwraith, McEacharn & Co. Ppty. (Ltd.), Billiter-square-buildings, London, E.C., to whom tenders by noon October. 3.

LONDON County Council require tenders by 11 a.m. Oct. 24 for supply of hand-power overhead crane, h.t. and l.t. cables and switchgear, &c., rotary converters and static transformers, for sub-stations. Specifications, &c., from the Clerk.

HACKNEY (London) Borough Council require tenders, by 7 p.m., Oct. 12, for supply of 100,000 pairs of white open type arc lamp carbons. Specification, &c., from the Town Clerk.

MANCHESTER Electricity Committee require tenders by noon Oct. 4, for supply and erection of a 4,000—4,500 kw. low-pressure exhaust type turbo-alternator. Specification from the Secretary, Town Hall, Manchester.

HASTINGS Guardians require tenders by Oct. 18 for the electric lighting of the workhouse premises, Ore, Hastings. Specification from Mr. S. Bumstead, 11, Wellington-sq., Hastings.

Tenders are invited up to Oct. 18 for the supply of 20 coin-in-the-slot attachments to the Postmaster-General's Department in WESTERN AUSTRALIA; up to Oct. 25 for supply to the Postmaster-General's Department in SOUTH AUSTRALIA of cable and paper sleeves; up to Oct. 2 for supply of 10,000 porcelain insulators to Postmaster-General's Department, TASMANIA; and up to Oct. 3 for supply of 42 miles of telephone cable to the Postmaster-General's Department, VICTORIA. Tender forms, &c. at the Commonwealth Office, 72, Victoria-street, London, S.W.

The Metropolitan Water and Sewerage Board, Albert-street, BRISBANE, Queensland, want tenders by noon Jan. 30 next for supply and erection of one, two or three complete units, each consisting of power generating plant and pump or pumps to lift not less than 6,000,000 gallons per day. Particulars from the Secretary, and forms from the Agent-General for Queensland.

DUNEDIN (N.Z.) Corporation require tenders by Nov. 1 for supply of (1) 500 B.H.P. vertical type gas engine or Diesel oil engine, suitable for rope driving an a.c. motor and d.c. generator; and (2) direct-coupled vertical type gas engine or Diesel oil engine and d.c. generator (800 kw. at 550 volts). Specification at 73, Basinghall-street, London, E.C.

WEST DERBY Guardians want tenders by Sept. 26 for 12 months' electrical supplies, &c. Forms of tender from the Clerk, Broughamterrace, West Derby-road, Liverpool.

BELFAST Markets Committee want tenders by Sept. 26 for wiring new abbatoir in Stewart-street. Specifications from the City Surveyor.

HACKNEY (London) Guardians want tenders (by 10 a.m. Sept. 27) for extension of the telephone systems at Homerton. Forms from the Clerk

MANCHESTER Tramways Committee require tenders by 10 a.m Oct. 3 for permanent way special track work, for points, tongues and hardened steel centres. Specificam Mr. J. M. McElroy.

LIVERPOOL Select Vestry require tenders for electric lifts and electric lighting at the workhouse. Names of intending tenderers should be sent by Sept. 30 to the Clerk, Brownlow-hill, Liverpool.

TULCEA (Roumania) municipality require tenders by Nov. 19 for electric lighting of the town.

Tenders are invited by the Municipal Council of PELOTAS (Brazil) for a 40 years' concession for the supply of electricity for power and lighting and the establishment and working of electric tramways. Tenders to Senhor Luiz M. da S. Pennafiel, Intendencia Municipal, Pelotas, up to 1 p.m. Nov. 14. A deposit (about £300) is required with each tender, to be increased by the successful tenderer to 25,000 milreis (about £1,670). Further particulars (in Portuguese) can be seen by British contractors at 73, Basinghall-street, London, E.C.

Tenders will be received at the Town Hall, SYZRAN, Russia, on Oct. 14, for the construction of an electric tramway and the supply of electrical energy for lighting.

TENDERS RECEIVED AND ACCEPTED.

Poplar (London) Electricity Committee have received the following tenders for two water-tube boilers with underfeed stokers and hot-air economisers:—

Babcock & Wilcox (2 motors) (*accepted*) £8,190; Stirling Boiler Co., £7,673 (3 motors),* £7,202 (4 motors), £7,983 (2 motors);* Howden Boiler Co., £8,200 (3 motors),* £8,408 (4 motors),* £8,608 (2 motors); Clarke, Chapman & Co., £8,571; Fraser & Chalmers, £10,498. *Not to Specification.

The borough electrical engineer (Mr. J. H. Bowden) thought the tender of Messrs. Babcock & Wilcox should be accepted, but instead of both boilers being fitted with underfeed stokers and hot-air economisers, only one should be fitted in this manner and the other with close link travelling grate, with water economiser and induced draught. After considering the facts the Committee decided to recommend the acceptance of the tender of that firm.

For supply and erection of a 30-ton electric overhead travelling crane the following tenders were received by the Poplar (London) Electricity Committee:—

Royce (Ltd. (*accepted*). £960; Chatteris Engineering Co., £845; Jas. Carrick & Sons, £912; A. Jack & Co., £950; S. H. Heywood & Co., £961 and £1,060; Cowans, Sheldon & Co., £995; J. Booth & Bros., £965; C. & A. Musker, £998; Marshall, Fleming & Co., £1,010; Babcock & Wilcox, £1,025; Stothert & Pitt, £1,040; Howden Boiler Co., £1,045, £1,104, £1,134 and £1,290; Sir William Arrol & Co., £1,046; Herbert Morris & Bastert, £1,062; Ransomes & Rapier, £1,155; Carrick & Ritchie, £1,169; Alex. Chaplin & Co., £1,220; J. Carter & Sons, £1,295; Craven Bros., £1,310; Jas. Spencer & Co., £1,320; J. Smith, £1,325; J. Henderson & Co., £1,605 and £1,620.

The contract for an extension to existing coal conveyor has also been placed by Poplar Council with Babcock & Wilcox at £373. Consideration of the tenders for an overhead bunker and for a combined coal elevator and conveyor has been deferred.

Farnham Gas and Electricity Co. have placed the following tenders for generating plant:—

Mirrlees, Bickerton & Day, two high-speed Diesel engines, two 90 kw. alternators, with d.c. exciters, &c., £3,795; Spagnoletti Limited, switchboard (with additions), £727.

The consulting engineers are Messrs. Handcock & Dykes.

The tender of the Corona Lampworks (Ltd.), Aschem-street, St. Pancras, N.W., has been accepted for the whole of the metal filament lamps for the Queen's Theatre, Shaftesbury-avenue, where the new comic opera "Bonita" is being produced by Mr. Courtneidge.

Auckland (N.Z.) Council have accepted the tender of Siemens Bros. Dynamo Works for electric power plant, including two Bellis-Siemens direct-coupled alternators of 1,000 kw. and two others of 600 kw. each, with boosters, balancers, switchboards, &c. The total amount of the contract is over £37,000.

Mr. C. W. Webster has obtained an order (through Messrs. McIlwraith, McEacharn & Co. Ppty., Ltd., of London) to supply Melbourne City Council with a large quantity of flame carbons, approximating 700,000 ft.

Mr. Webster's firm (the Compania Fabril de Carbones Electricos, of Barcelona) are manufacturing highest grade beacon flame carbons, and he has lately received contracts and orders to supply many Corporations in this country.

Southwark (London) Council have accepted the following tenders:

Siemens Bros. Dynamo Works, 40 kw. motor-generator and switchgear, £121. 15s.; British Insulated & Helsby Cables, 440 yds. one l.t. cable, £97. 10s.; Reavell & Co., air compressor for cleaning the generators, £64. 10s.

Blackburn Guardians have accepted the tender of J. W. Garsden & Co. for an electric heater at £192. 10s., in place of a compressed air heater previously recommended for acceptance.

Digitized by Google

North Ormesby Council have accepted the tender of Baker Bros. for a fire-alarm installation at £68.

Sherburn Council have accepted the tender of Haydn Harrison for 36 250-volt 50 c.p. Osram lamps.

Mansfield Education Committee have accepted the tender of the Mansfield Engineering Co. for wiring Carter-lane schools at £40.

Waterloo Council have placed an order with H. Leake & Co. for the electric lighting of the secondary schools at £421.

Brighton Guardians have accepted the tender of G. Virgo for electric light fittings at £37.

Warrington Education Committee have accepted the tender of H. Bibby for wiring Evelyn-street schools at £344. 10s.

Westinghouse Contracts.—Among recent orders secured by the British Westinghouse Electric & Mfg. Co. are the following :—

R. Jeffry, two 140 k.v.a. alternators, trans. switchgear, motors, compressors, &c.
Montague Higginson & Co., one 150 kw. alternator, exciter and rheostat.
London County Council, 100 sets controllers, &c., and 10 magnetic brakes.
Hetton Coal Co., one 250 H.P. motor controller.
Noyes Bros. (for Adelaide tramways), 40 T.I.F. controllers.
Ditto (for Sydney), two 60 kw. d.c. generators.
Met. Dist. Railway Co., one 1,200 kw. rotary converter, transformers and switchgear.
British Insulated & Helsby Cables, one 200 kw. rotary converter, transformer and switchgear.
Port of London Authority, three 300 kw. rotary converters.
London Electric Railways Co., one 1,500 kw. rotary converter and three 550 k.v.a. transformers.
National Telewriter Co., 50 14,060 double-gear machines.
Consolidated Gold Fields of S. Africa, one 275 k.v.a. and one 940 k.v.a. steam engine sets.
Ocena Cons. Co., two 200 kw. d.c. generators with equipment and switchgear.
Crains Limited, one 85 kw. a.c. generator and exciter, six 20 H.P. and various motors.
Rintoul & Davis, one 118 kw. motor-generator set.
Cambrian Combine, one 35 kw. motor-generator set.
Workington I. & S. Co., one 80 kw. d.c. generator, haulage gear, pumps and control gear
Randfontein Gold Mining Co., one electric main hoist.
Ingersoll, Rand & Co., two 540 H.P. d.c. motors.
A. Ransome & Co. (for Grangemouth Docks), one 2 H.P., two 10 H.P., one 30 H.P., two 50 H.P., 220-volt G. motors, starters and switchboards.
Greenwich Inlaid Lin. Co., one 100 H.P., one 50 H.P. and one 35 H.P. a.c. motors and control gear.
Sir W. G. Armstrong, Whitworth & Co. (for Murray Docks), six 20, 2,315 G., six 4 H.P. 1,609 G. 460 volt motors and control gear.
M. Samuel & Co., one 65, one 64, one 25 a.c. motors and pumps.
Central Argentine Railway Co., eight motors aggregating 70 H.P., 500 volt FFB motors.
Staveley Coal & Iron Co., 16 10 H.P. motors and 4,000 k.v.a. transformers.
Babcock & Wilcox, 16 motors aggregating 30 H.P., 220 volt.
Gt. Indian Pen. Railway, G. motors, control gear and spares.
Leys Malleable Castings Co., six 12 H.P. 550 FFB motors and panels (one back geared).
Agar, Cross & Co., various CCB motors and auto-starters, one 20 H.P. 565 FFB and starting rheostat.
Thomas Barlow & Sons, two 312 H.P. slip-ring motors, &c.
Powell, Duffryn & Co., Elliot pit pump ventilation.
Daimler & Co., switchgear.
City of Santos Improvement Co., spare parts for equipments supplied.
Metropolitan Railway Co., one 1,200 kw. rotary transformer, switchgear, &c.
Stalybridge Tramways, transformers.
West Ham Corporation, transformers and switchgear.
Strain & Robertson (Alianza Co.), transformers and switchgear.
Daimler & Co., transformers and switchgear.

Government Contracts.—The British Government Departments have placed contracts with the following firms during August :—

War Office.—British Insulated & Helsby Cables, W. T. Henley's Telegraph Works Co., Hooper's Telegraph & India Rubber Works, India Rubber, Gutta Percha & Telegraph Works Co., London Electric Wire Co. & Smiths, Midland Electric Wire Co., St. Helen's Cable & Rubber Co., and Siemens Bros. & Co., electric cable, &c. ; J. A. Prestwich & Co. and Willans & Robinson, oil engines ; Siemens Bros. Dynamo Works, generating set.

General Post Office.—British Insulated & Helsby Cables, bell sets, flexible cords and bronze wire ; London Electric Wire Co., flexible cords ; British L. M. Ericsson Mfg. Co., plugs and lightning protectors ; Western Electric Co., paper core cables and extension of telephone apparatus at Mayfair Exchange ; Medway's Safety Lift Co., electric lifts for W.C. London) District Post Office.

India Office.—J. Stone & Co., armatures and electrical fittings.

Crown Agents for the Colonies.—Western Electric Co., telephones, &c. ; Marconi's Wireless Telegraph Co., wireless installation.

H. M. Office of Works.—Siemens Bros. & Co., cables for Imperial College of Science.

BUSINESS NOTICES.

A temporary (Post Office) telephone exchange was opened yesterday (Thursday) at the Electrical Exhibition, Olympia, London. All connections are being made via "City" Exchange.

The partnership between Wm. and Jacob T. Walmsley and Ernest F. Lucas (trading as the W. & L. Electrical Engineering Co.), Granville-street, Swinton, near Manchester, has been dissolved. Debts by Messrs. W. and J. T. Walmsley, who continue under the old style.

The address of the International Institute of Technical Bibliography and of "Engineering Abstracts" has been removed to 68, Hampstead-way, N.W.

Directive Wireless Telegraphy.—In order to comply with the requirements of the Patents and Designs Act, 1907, apparatus for the Bellini-Tosi directive system has been manufactured by the Helsby Wireless Telegraph Co. under licence from the patentees.

Agency.—A German firm of accumulator manufacturers advertises for a London firm with a connection among motor-car makers, &c., to take over the sole agency of their portable accumulators.

Plant for Sale.—Mr. Alex. Mein, Station-street, Stratford, London, E., advertises for sale a Crompton three-phase alternator, switchboard, &c.

Mr. D. Spero, 31, Duke-street, Aldgate, London, E.C., advertises for sale a steam engine, two dynamos, switchboard, battery, motor, &c.

Plant Wanted.—The New Transport Co., Bath House, Holborn Viaduct, London, E.C., require a second-hand 10 H.P. (12 H.P.) motor, single-phase, 100 volts, 40 periods.

An advertiser requires a portable petrol-driven electric light plant for cinematograph theatre. Applications to Mr. A. West, Illawarra House, All Saint's-road, Bromsgrove.

Patents Development.—The owners of patents No. 23,501/99, relating to "Improvements in vacuum tube lighting," and No. 12,582/02, relating to "An improved system of electric lighting," desire to negotiate with electrical engineers with the view of granting licences. Applications to Messrs. Lloyd Wise & Co., patent agents, 46, Lincoln's Inn Fields, W.C.

The proprietor of patent No. 20,324, 1902, for "Improvements in conduits for electric cables," desires to grant manufacturing licences. Applications to Mr. C. Lean, patent agent, 231, Strand, London, W.C.

The owners of British patent No. 23,778/1907, for "Improvements in the manufacture of electric resistances," desire to sell their patent rights or to grant licences thereunder. Particulars from Messrs. Day, Davies & Hunt, patent agents, 321, High Holborn, London, W.C.

Business for Sale.—The business of an electric motor manufacturing company is advertised for sale in another column.

BANKRUPTCIES, LIQUIDATIONS, &c.

The official receiver (Mr. H. E. Burgess) has issued his report in the liquidation of J. G. Childs & Co. (Ltd.)

The accounts show total liabilities £30,202, of which £22,978 is unsecured, the assets valued at £3,410 being absorbed in the debenture claims. The deficiency to the contributories is estimated at £41,060. The company was formed in Dec., 1901, with a capital of £20,000 to acquire and carry on the business of electrical engineer belonging to Mr. J. G. Childs. The trading, which consisted chiefly of the manufacture and sale of electrically-controlled lifts, was carried on throughout at a loss, and since Feb., 1908, with the assistance of debentures. In the following October the directors resolved to take up the manufacture of wind turbines, incorporating certain inventions of Mr. Childs relating thereto. Considerable expense was incurred in developing and advertising the wind turbines, and a small number was sold, about five in this country and four abroad. On March 31 last Mr. H. W. Freshwater was appointed receiver on behalf of the debenture holders and is realising the company's assets and completing a number of unfinished contracts. The insolvency of the company is attributed chiefly to contracts having been undertaken at prices which were not remunerative, and to excessive expenditure in carrying on the business.

A meeting of creditors of Silicaware (Ltd.) will be held at the offices of Messrs. Gundry, Straus & Soper, 7, Gt. Winchester-street, London, E.C., on Oct. 17.

A first and final dividend of 3s. 9½d. will be payable on Sept. 26 at 12, Duke-street, Bradford, to creditors of Wm. Hy. Illingworth (trading as the Yorkshire Metal Filament Lamp Co.), 30, Pellon-lane, Halifax.

The trustees (Mr. Chas. H. King, 26, Baldwin-street, Bristol) in the bankruptcy of Valentine Geo. Burkitt, electrical engineer, 38, Park-row, Bristol, has been released.

The liquidator (Mr. C. Mercer, 14, Bedford-row, London, W.C.) of Electrical Instrument Manufacturers (Ltd.) has been released.

COMPANIES' MEETINGS AND REPORTS.

CLEVELAND & DURHAM ELECTRIC POWER (LTD.)—The report of the directors for the year ended June 30 states that the gross profits for the year amounted to £20,973, compared with £12,942 for the previous year. After providing for debenture and other interest the net profit was £8,342, which it is proposed to carry forward. During the past year the capital expenditure was £9,107. The connections to the company's system aggregated 40,460 H.P., an increase of 4,177 H.P. In addition 12,500 H.P. has been recently contracted for and other important negotiations are proceeding. Arrangements are being made to work further waste heat generating stations at the Tees Furnace Co.'s Lackenby Ironworks, Redcar ; the Port Clarence works, Messrs. Bell Bros., Middlesbrough ; the Ayresome Ironworks of Mills & Co., and also at the Redcar Ironworks of Walker Maynard & Co. The scheme for the rearrangement of the capital was confirmed by the Court in December last and the capital now stands reduced by £299,915.

DICK, KERR & CO. (LTD.)—The directors' report for the 12 months to June 30 last states that the profits earned amounted to £37,994. 3s. 2d. Out of this debenture interest and trustees' fees had been paid and there had been reserved the sum required to provide for the premium payable on redemption of debenture stock. These items absorb £12,060. 8s. 11d., leaving £25,933. 14s. 3d., added to the profis brought forward from last year (£42,858. 0s. 8d.) making £63,191. 14s. 11d. available to pay the 6 per cent. preference dividend (£18,300), and an ordinary dividend of 5 per cent. (less tax) (£13,000), carrying forward £36,891. 14s. 11d. Notwithstanding continued competition in all branches of the business during the past year, the directors are pleased to submit accounts which show considerable improvement in comparison with the two preceding years. Should the present hopes of the directors be fulfilled the prospects are encouraging.

DIRECT UNITED STATES CABLE CO. (LTD.)—The report of the directors states that for the six months to June 30 the half-year's revenue, after deducting out-payments, amounted to £46,229. 17s. 11d., compared with £58 555. 0s. 5d. for the corresponding period of 1910, a decrease of £12,326. 2s. 6d. This falling-off is due to the Western Union Telegraph Co. having departed from the arrangement that has been in force since 1882, by withholding traffic collected by that company in America which has hitherto been transmitted over the cables of the Anglo-American Telegraph Co. and of this company. Working and other expenses during the six months, including income tax, amounted to £27,743. 19s. 4d., compared with £25,277. 6s. in the corresponding six months in 1910, an increase of £2,471. 13s. 4d., which is accounted for by expenses at the Harbour Grace station, established in the latter part of last year and which appear now for the first time in the accounts. The reserve fund account, after being debited with the cost of maintenance of cables, balance of expenditure on fire extinguishing plant at Ballinskelligs station, expenditure in connection with the diversion of the cable to Newfoundland, and the transfer to revenue of £7,168. 6s. 7d. (to provide for the dividend and bonus paid on July 31 last), and being credited with interest on the investments and profit on sale of securities, stands at £512,323. 2s. 11d., compared with £533,024. 5s. 1d., at June 30, 1910, showing a decrease of £20,701. 2s. 2d. If, however, the expenditure of a capital nature upon the company's properties and in connection with the diversion of the cable (£31,203. 19s), which has been charged to reserve during the year, be taken into consideration, it will be seen that £10,502. 16s. 10d. has been added to reserve during the year, after charging against it cost of maintaining and renewing the cables.

As the result of negotiations, extending over many months, an agreement, of which particulars accompany the report, has been provisionally entered into by the directors with the Western Union Telegraph Co. This agreement will [as mentioned elsewhere] be submitted to the shareholders at an extraordinary general meeting at the conclusion of the 68th ordinary general meeting. The negotiations were in progress in July when the final accounts have hitherto been issued, but in the circumstances the directors considered it was not in the interests of the shareholders then to issue them. They therefore deferred the publication of the accounts, paying a dividend and bonus for the quarter to June 30 last at the same rate as for the corresponding quarter in 1910. Thus a dividend of 4 per cent., with a bonus of 1 per cent., making 5 per cent. in all, was paid to the shareholders during the past financial year.

[Reference is made to the agreement between the Direct Company and the Western Union on p. 943.]

DUNDEE, BROUGHTY FERRY & DISTRICT TRAMWAYS CO. (LTD.)—The directors report for the year ended July 31 states that the profit (including amount brought forward), after providing for debenture interest, was £5,163. The directors propose placing to renewals fund £600, to sinking fund for redemption of debenture stock £600, paying a dividend on the ordinary shares at rate of 2 per cent. per annum for the year, and carrying forward £388. The earnings of the tramways remain approximately the same as last year, the traffic receipts showing a decrease of £46.

UNDERGROUND ELECTRIC RAILWAYS CO. OF LONDON (LTD.)—At the half-yearly meeting on Tuesday the chairman (Sir Edgar Speyer) said the accounts showed good progress, but the dividends did not represent a fair return on the large capital invested. The receipts for the half-year were £158,536, an increase of £10,921, and the net revenue was £39,497, a gain of £13,104. The income from investments was £105,975, or £15,678 more than in the first half of 1910, chiefly due to the better earnings of the London Electric Railway Co.

UNITED ELECTRIC CAR CO. (LTD.)—At the meeting on Wednesday Mr. Geo. Richardson said that the directors regretted the smallness of the profit (£4,420), but they considered it perfectly satisfactory in face of the stagnation in the car-building trade. The Company had had a very fair share of the limited business given out, but the prices had been cut very fine, and the output had been so small that necessarily there had been a very bare margin of profit after taking into account the fixed charges. Financially the company was in an exceedingly strong position, and the prospects were better than for some years past, the order book being in a satisfactory condition. In regard to the Hadley and Trafford Park works, the directors regretted the unavoidable loss, but both works had been disposed of on the best possible terms.

YORKSHIRE ELECTRIC POWER CO.—At the meeting on Tuesday the chairman (Mr. A. G. Lupton) said that the company showed the same steady progress as for some years past. The gross profit for the past half-year was £6,633, against £4,950 for the corresponding half-year of 1910, and £2,598 for 1909, whilst the net profit had increased from £1,069 in 1909 to £2,621 in 1910, and £4,137 for 1911. They had, however, to meet a new item of expense for dividend on the cumulative preference shares, which amounted to £1,136 for the half-year. There had been a general increase in the sale of energy to all classes of customers, textile, colliery and general power users, and the directors were glad to note that that also was the case with local authorities, and the Electrical Distribution Co, showing a growing appreciation of the advantages gained by purchasing in bulk. They had taken a supply for Ossett and the urban districts of Horsforth, Farsley, Gomersal, Liversedge, Hipperholme, Sowerby Bridge and Castleford, and steps were being taken to apply during the 1912 Session for further orders. Since the issue of the report there had been a serious breakdown of the generating plant at Thornhill, which would entail considerable expenditure for repairs, and occasion a loss of revenue owing to delay in connecting new customers Temporary plant had been installed to help over the difficulty. There were more inquiries on hand from likely customers than at any time since the company started, so that the prospects were very encouraging. The result of the company's appeal to the Board of Trade against the refusal of Batley Council to lay a main through that borough was in the company's favour. The demand on the company by collieries for hauling, pumping, ventilating, winding and other purposes continued to grow. They were already supplying pits in the areas of Thornhill, Ravensthorpe, Mirfield, Kirkheaton, Emley, Lepton, Allerton Bywater, Stanley, Ledstone, Dodworth and Wakefield Rural, During the half-year there had been further extensions of mains and the company had now trunk feeders extending from Horsforth on the north to the Barnsley coalfield, and Penistone on the south, and from Castleford on the east to Sowerby Bridge on the west, with numerous branches on the main routes. Further extensions were being proceeded with, and arrangements made with a number of customers for supply which would yield increased revenue in the future.

MORTGAGES AND CHARGES.

CORONA LAMP WORKS (LTD.)—Issue, on Aug. 22, 1911, of £200 debentures, part of a series of which particulars have already been filed.

HINDHEAD & DISTRICT ELECTRIC LIGHT CO. (LTD.)—Issue, on Sept. 8, of £200 debentures, part of a series of which particulars have already been filed.

MAXIM LAMP WORKS (LTD)—Charge on company's undertaking and property, including uncalled capital, dated Sept. 4, 1911, to secure all moneys due or to become due from the company to Barclay & Co.

CITY NOTES.

MEMORANDA (Sept. 21).—**Bank rate 4 per cent.** (since Sept. 21, 1911.) **Price of silver, 24⅛d. per oz. Consols 77⅛—77⅜ for money; 77⅛—77⅜ for account. Consols Pay Day, Oct. 5; Stock and Shares Continuation Days, Sept. 26 and Oct. 10; Ticket Days, Sept. 27 and Oct. 11; Pay Days, Sept. 28 and Oct. 12; Mining Shares Carry Over Day, Sept 25.**

PRICES OF METALS (London).—*Copper*, cash, 54⅛; three months, 55⅜. *Lead*, English, 15⅝—15⅞; Foreign, 15¼—15½. *Spelter*, 27⅛—27⅜. *Tin*, English, 180—181; Foreign, cash, 176¾; three months, 175¾. *Iron*, Cleveland, cash, 46/6½, three months, 47/4½.

ANGLO-AMERICAN TELEGRAPH CO. (LTD.)—An extraordinary general meeting of this company will be held at Winchester House, London, E.C., on Friday next, Sept. 29, at 12 noon, for the purpose of considering and, if thought fit, passing resolutions to amend the company's memorandum of association in view of the arrangement with the Western Union Telegraph Co., referred to on page 943.

BROMLEY (KENT) ELECTRIC LIGHT & POWER CO. (LTD.)—The directors have declared an interim dividend at the rate of 4 per cent per annum (2s. per share), less tax, on the ordinary shares for the half-year to June 30.

CALCUTTA ELECTRIC SUPPLY CORPN. (LTD.)—The number of units delivered to consumers during the four weeks ended July 23 were 912,348, compared with 794,120 in the corresponding four weeks of 1910. For the four weeks ended Aug. 25 the figures were 968,855 (compared with 824,917).

HOVE ELECTRIC LIGHTING CO. (LTD.)—The directors have declared an interim dividend on the ordinary shares at the rate of 8 per cent. for the six months to June 30.

KALGOORLIE ELECTRIC TRAMWAYS (LTD)—This company's traffic receipts for August were £3,853. Aggregate from Jan. 1, £27,657.

MADRAS ELECTRIC TRAMWAYS (1904) (LTD)—The traffic receipts of this company for the fortnight ended Sept 15 were R24,324 (increase R2,336). Aggregate from Jan. 1, R377,848 (increase R32,228).

METROPOLITAN ELECTRIC TRAMWAYS (LTD.)—The directors have declared an interim ordinary dividend on account of the year 1911 at the rate of 6d. per share (less tax), payable Oct. 16.

SHAWINIGAN WATER & POWER CO.—A dividend of 1½ per cent. has been declared for the quarter ended Sept. 30.

SIR W. G. ARMSTRONG, WHITWORTH & CO. (LTD.)—The directors announce an interim dividend at the usual rate of 10 per cent. (tax free) on the ordinary shares.

WINNIPEG ELECTRIC RAILWAY CO.—A quarterly dividend at the rate of 12 per cent. per annum has been declared.

NOTES.

The Public and the Electrical Exhibition.

HOWEVER pleased the Executive Committee may feel at getting together such a fine collection of electrical manufactures at Olympia, and at acquainting the trade, through the technical Press, with the Exhibition, as a fact it has completely failed in whatever methods it adopted for bringing the public to the show. The Exhibition posters are indifferent, to say the least, and there have been no lay Press advertisements and few "write-ups" of the Exhibition. Such matter as has been published is quite inadequate to the needs of the Exhibition. Until Wednesday evening the Exhibition was innocent of a band. As we go to press we hear general complaints that the first week of the Exhibition has been wasted, and to many of the exhibitors this is a serious matter, as can easily be understood. Four days after the Exhibition had been opened an attempt was made to obtain the assistance of the technical Press in preparing articles of a popular nature which might be inserted in the daily papers. At considerable inconvenience we placed ourselves at the disposal of the authorities, and were joined by several contemporaries; but the originators around whom the movement was to have crystallised unfortunately failed to put in an appearance. It was also understood that the exhibitors were being approached to subscribe to a general fund from which suitable advertisements could be inserted in the daily papers. The co-operation of the technical Press was sought with a view to the placing of these announcements in the right quarter. This idea is a good one, and it seems a pity that it has not been carried further. The extraordinary part of the whole proceeding is that a week after the opening of the Exhibition the authorities have awakened to a fact which should have impressed itself upon them at least three months ago.

THE General Electric Co., with its usual enterprise, arranged a Press view of its exhibits last Monday, and a considerable number of the London dailies put in an appearance. From what we can gather, some of them became acquainted with the Exhibition and its objects for the first time on that occasion. Mr. HIRST explained the popular nature of the Exhibition, and the fact that there was an innumerable variety of electrical appliances which would interest the public if they could be brought to realise that such apparatus was on view. It certainly looks as if something has misfired in the arrangements, and, although it is not now too late, a valuable week has been practically thrown away, and this must reflect on the general success of the Exhibition at its close.

What Should the Exhibition Be?

THE management seem to have quite lost sight of the important fact that the object of such an Exhibition should be to attract and educate the public. There is an immense field for the domestic applications of electricity, and nowhere can these be so well demonstrated as at an exhibition. But, we need hardly remark, it is essential to get the public to attend if this object is to be attained; and it is well to remember that the public, when they do attend, require education to be of a free-and-easy kind. There is no subject that lends itself so well to popular demonstration as electricity. Admirable "side shows" can be made by lamp making, wireless telegraphy and telephony, high-tension

Digitized by Google

discharges, radiography, electric furnaces, and electric cooking; also by short lectures and demonstrations at stated intervals, and in many other ways.

It is all very well to say that such side-shows are commonplace; they are to the engineer, but not to the layman, and so long as the public is attracted by them they should be provided. Visitors are amused thereby, and almost unawares they pick up the desirable seeds of knowledge in the intervals. True, there are already demonstrations of electric cooking, but we doubt if many visitors are aware of them, for there is no daily programme or other means of knowing easily what is going on. The visitor is also repelled by the unattractive appearance of most of the stands, many of which look like melancholy shelters from bad weather. Why should there not have been some preconcerted scheme to give a pleasing effect? Surely our Continental friends would not plan an exhibition in this way; the Turin Exhibition is indeed an example of the proper method. These various sins of omission do not speak well for the commercial instincts of the management, whose object, we presume, is to make money; and we fear that if immediate steps are not taken to alter the arrangements drastically the Exhibition will be a failure, instead of being a well-merited success.

Electric Locomotives for Shunting.

In discussing the features and advantages of railway electrification authors have generally confined their attention largely to the passenger traffic side of the question. Although this is the aspect of the subject with which the public are more particularly concerned, and is therefore of wider interest, the result has been that comparatively little regard has been paid to goods traffic; whilst the less conspicuous, but by no means unimportant, shunting operations have, we believe, rarely been made the main topic of a discussion on the merits of electrification. Elsewhere in the present issue will be found an abstract of a Paper on the use of electric locomotives for shunting, read by Mr. A. H. Marshall before the Cleveland Institution of Engineers, in which the author makes out a very good case for electrical plant.

Owing to the system adopted on steam railways of stating average costs per engine-mile, based on an estimated number of engine-miles in the case of shunting engines, the actual cost of shunting by existing means is probably not fully ascertained. A steam locomotive is particularly ill adapted for shunting work, and its operating costs under these conditions are much higher than those of normal running. This is evident from the fact that even in a busy yard a shunting locomotive is standing for more than one-half the time it is in service. Moreover, an electric locomotive can accelerate more quickly and therefore is able to maintain a higher average speed, whilst its stand-by and maintenance charges are less than those of the steam locomotive. The handling of heavy short-distance goods traffic certainly seems to offer a promising field for electric operation, and unless the railway companies take the initiative in this direction, private owners are not likely to make the change except in special cases. One of the most interesting installations in this connection is that of the Harton Collieries, to which Mr. Marshall refers, where six electric locomotives are in use for shunting and two more are on order. At these collieries some 15 miles of electrified track will shortly be in operation.

The author's remarks on underground haulage are particularly worth attention. The Cleveland ironstone mines are, we believe, very suitable for the introduction of either trolley or accumulator traction, as there is generally plenty of headroom, a good roof and practically complete absence of gas. The conservatism of the mine managers will doubtless require much time and persuasion to overcome, but as these mines are installing electrical apparatus for most purposes, the application to electric traction should not now be long postponed. English manufacturers, therefore, should certainly see that they are prepared to meet this demand for electric locomotives of the type required, and they should endeavour to hasten the conversion.

A Neglected Profession.

The numerous physicians who from time to time attempt to diagnose the ills of the electrical industry often hit upon "overcrowding" as a cause of the malady. But it has been left for Mr. T. E. Elder, in a letter to the "Daily Mail," to apply the above epithet to our profession. This letter is certainly not without its extraordinary side, for, after calling attention to the difficulty of obtaining properly trained young men (evidently with some practical experience) and to the possible necessity of importing assistants from the Continent if the present state of affairs continues, Mr. Elder concludes: "Electrical engineering still offers a much larger field for invention and discovery and personal advancement for merit than any other comparable career." Even if all this be conceded, there is one salient feature of the electrical engineering profession at the present time which more than off-sets all these advantages, namely, the poor financial outlook. The young engineer's education is lengthy and expensive (for instance, the firm with which Mr. Elder is connected charge £300 for allowing pupils to pass through their shops), and not only is the immediate return for this expenditure small, but it may be some years before a living wage is earned. This being the case, it is not surprising there should be a falling-off in the supply of young engineers for subordinate positions. For no array of other advantages, such as Mr. Elder details, can compensate the present commercially minded generation for those of a well-lined trouser-pocket. It seems to us to be high time that the heads of the electrical engineering profession recognised that to obtain good men, even in times of depression, they must offer adequate salaries; for a man of some initiative, even when trained as an electrical engineer, will not be deterred from changing his profession if he finds that he obtains a better position by so doing.

The 20-watt 200-volt Osram Lamp.

We announced exclusively in our Exhibition report last week that the General Electric Co. would be exhibiting a 16 c.p. 20-watt 200-volt lamp at Olympia. The technical and daily Press were given an opportunity on Monday last, on the special invitation of the Company, of examining this

Digitized by Google

interesting lamp at their stand. It is a jointless filament lamp, and the makers claim for it a high efficiency and long life. The introduction of this lamp comes at an opportune moment, and, though it may not be welcomed by the station engineer, it is certain to result in an increase in the number of his consumers. The carbon lamp is still used to a considerable extent on the higher voltage circuits. The new Osram should displace these inefficient light units. The small size of the lamp is another feature in its favour. It can be used with shades intended for carbon lamps, also in watertight fittings, table lamps, brackets, standards, &c. The demonstrations of the lamp at the Exhibition are such as to show that it is in no way fragile—at any rate in the early stages of its life. The actual number of burning hours has yet to be proved, but we understand, from experiments made by the General Electric Co., that the life will be such as to encourage the wide use of the lamp. We must compliment the Company on the production of a lamp of this character at this particular period, because interest is being created in the drawn-wire lamp, and the new Osram will take its place prominently among these newer patterns.

Steam Turbine as a Monument.—It will be remembered that the 5,000-kw. steam turbines erected in 1903 in the Fisk-street station of the Commonwealth Edison Co., of Chicago, had a short life, being replaced a year or two ago by units of 12,000 kw. capacity. The "Electrical World" states that one of these 5,000-kw. turbines has now been erected in the centre of a park in the grounds of the General Electric Co. at Schenectady, to serve as a memorial of the rapid development of the steam turbine in central station service.

Experimental Electric and Gas Lighting in Manchester.—It is stated locally that the electricity and gas departments of the Manchester Corporation are about to undertake a series of comparative tests on street lighting. The gas department has arranged to light Moseley-street and St. Peter's Square, and the electricity department has in hand the lighting of Albert Square, Piccadilly and Portland-street. In the course of the next few months there will be a trial of the two systems of street lighting. The initial cost, the expense of upkeep, and the quality of the illumination will be recorded, and the City Council will then determine which system of public lighting has the advantage. As regards the electric lighting of Albert Square, sixteen of the 6 amp. Gilbert type of enclosed arc lamps have been replaced by a similar number of 10 amp. "Metro-Flam" arcs made by Messrs. Johnson & Phillips. The height of the new flame arcs is 22 ft. 6 in. from the ground level, instead of 17 ft. as at present. The maximum candle-power of each of the new "Metro-Flams" is not less than 2,500. The old and new lamps burn respectively for 80 hours and 130 hours without retrimming. They are all switched on from a central position, and the height of the lamps has been so arranged as to give the desired illumination without "glare." In Portland-street central lighting has been adopted as far as possible, arc lamps being suspended from duplicate cross-span wires attached to rosettes fixed on the fronts or corners of the buildings. Where this course has not proved feasible, side poles with long arms are fixed so as to bring the lamp central with the street. Provision is made for the raising or lowering of the lamps to suit the best conditions for illumination.

Cable Interruptions and Repairs.

Sharman System of Wireless Telephony.—Through the courtesy of the proprietors of the "Daily Mirror" our representative was enabled to be present on Wednesday last at a demonstration of wireless telephony between ship and shore given by Mr. A. W. Sharman and Mr. Thorne Baker, with the apparatus invented by the former and called by him the "Cymophone." The experimental stations were situated at Pegwell Bay near Ramsgate, one on shore and the other in a boat in the bay. The system employs two earth connections at either end, its chief novelty being the utilisation of energy stored in an inductance in the transmitter. Telegraphy and telephony are practicable with the same apparatus on switching over from the microphone to a buzzer. The instrument is extremely portable and of very low cost, and should, therefore, be useful in many cases where more complicated and expensive apparatus would not be suitable. At the demonstration speech was transmitted in both directions.

Electric Lighting of Trains.—The "Engineer" remarks that some interesting details regarding the electric lighting of the Great Western trains were given in a Paper recently read before the Great Western Railway Lecture and Debating Society. A special staff of 15 men is distributed throughout the system to supervise electric lighting matters, and reports are despatched daily to the head office as to the repairs carried out on the electrical equipment. An interesting system is adopted in connection with the accumulators. For this purpose an indicator board is used, divided into three sections, each representing a year. Each of these divisions is further subdivided into months, and a row of pins is affixed opposite the name of each month. Every coach in use carrying a battery of accumulators is represented on the board by a tab bearing its number, one side of the tab being painted red and the other green. When the battery is first put in use the green side is placed outwards, the tab being affixed in the row corresponding with the month when it was put in service. The accumulators on each coach are thoroughly overhauled every 11 months, and by this time the tab has been altered in position, so that it is 12 divisions away from its original place, each division representing a month. The red side of the tab is then turned outwards, and the inspector is notified that the accumulators of that particular coach require immediate overhauling.

Wireless Telegraph Developments.—"The Times Engineering Supplement" states that preliminary experiments have been conducted by Capt. Brenot with an equipment for wireless telegraphy, fitted on a Henri-Farman biplane. The energy is furnished by the Gnome motor of the aeroplane, which drives a special magneto and charges the antenna direct. The antenna consists of a bronze wire, 120 m.(400 ft.) long and 1 mm.(0·04 in.) in diameter, which passes through insulating tubes and is unwound behind the aeroplane. The wire can be cut in case of need, as, for example, if at the moment of landing there is no time to wind it up. With this apparatus it has been found possible to send messages regularly over distances of from 60 km. to 80 km. (37½ to 50 miles). The total weight of the equipment, including the wire, is 21 kg. (46 lb.).

Observant persons in the neighbourhood of St. Martin's le Grand may have noticed two masts which have recently been erected on the roof of the building known as G.P.O. West. We are informed by the Engineer-in-Chief to the Post Office that these masts, which are 50 ft. high, and stand about 240 ft. apart, support a system of bare copper wires forming the antenna or aerial of a wireless station in connection with the laboratory of the G.P.O. Engineering Department. The main purpose of this installation is experimental. Developments in the theory and practice of wireless communications are proceeding at a rapid rate, and in the projection of new stations as well as in the maintenance of existing stations much work of an experimental nature has to be undertaken. Traffic considerations permitting, it has often been necessary in the past to convert temporarily a commercial station into a laboratory or test room for experimental purposes. The wireless equipment referred to will allow experimental work to be carried out with greater facility and at less expense than heretofore, and at the same time will enable new devices which inventors sub-

Digitized by Google

mit to the Postmaster-General from time to time, and which they claim to be improvements on the apparatus actually in use, to be placed under closer observation than formerly and to be tested under practical conditions.

The Westmorland and Cumberland Yeomanry have introduced for cavalry operations two portable Marconi wireless telegraph sets. These are carried on four pack saddles, and maintain communication over a distance of about 40 miles. Each station has two 60 ft. masts supporting horizontal aerial wires. Power is supplied by a small air-cooled petrol motor, permanently mounted on one side of a rigid but adjustable saddle, and the dynamo is mounted similarly on the other side. To bring them into action the complete saddle is taken from the pack animal and placed on the ground, when the dynamo and petrol motor are connected with a self-adjusting shaft. The wireless apparatus is contained in three weather-proof boxes, which are placed on top of each other, and are instantly ready for use. The earth system consists of a short length of tough metallic netting which is rolled out on the ground, and is plugged into a suitable socket in the receiver. The generator is connected to a transformer by a 50 ft. length of armoured flexible cable. These portable stations were specially designed by the Marconi Company that they should be capable of easy and rapid transportation and of effecting a ready means of communication between units of the main body. The time taken in erecting the sets ready for work is nine minutes, and for dismantling and repacking six minutes.

Rating of Electrical Machinery.—An interesting Report has been prepared by Mr. C. Le Maistre, General Secretary of the International Electrotechnical Commission, on the rating of electrical machinery. The Report contains extracts (set out in English and French, as is customary with all matters relating to the Commission) from the rules adopted in varous countries for the testing and rating of electrical machinery, and it has been drawn up to facilitate the work of the various Electrotechnical Committees in considering this question of rating. Since continuous-current machinery will probably be considered first, the Report is mainly confined to this class of apparatus. In an interesting preface, Prof. Elihu Thomson, president of the Commission, mentions that a study of this Report will show that the supposed difficulty in bringing about international agreement on the subject of the rating of electrical machinery is not really so great as in the case of nomenclature, symbols, &c., which problems have been successfully tackled by the Commission. The Rules from which extracts have been made are as follows: *Belgium.*—"Prescriptions normales" for the reception of electrical machines and transformers, issued by the "Chambre Syndicate des Electriciens Belges." *France.*—General instructions for the delivery and reception of electrical machines and transformers, issued by the "Union des Syndicats de l'Electricité," and the regulations for tenders, supply and testing of electrical machines and transformers, issued by the "Association Alsacienne des Propriétaires d'Appareils à Vapeur." *Germany.*—Standard Rules for the utilisation and testing of electrical machines and transformers, issued by the "Verband Deutscher Elektrotechniker." *Great Britain.*—Report of the Engineering Standards Committee on "Electrical Machinery." *Sweden.*—Rules for the testing and reception of electrical machines and transformers, issued by the "Association of Swedish Engineers." *United States of America.*—Standardisation Rules of the American Institute of Electrical Engineers. Copies of the Report may be obtained from the General Secretary of the Commission, 28, Victoria-street, Westminster, at a price of 4s. 2d. or 5 fr. or $1 per copy.

"The Electrical Conductivity and Constitution of Alloys."—At the annual autumn meeting of the Institute of Metals recently held at Newcastle, Dr. W. M. Guertler read a Paper on this subject. The aim of the Paper was to call attention to the property of electrical conductivity in its bearing upon the practical determination of the constitution of alloys. The so-called "equilibrium diagram" for alloys was, the author stated, now almost universally accepted as the basis for any systematic study of the properties of alloys, and hence it was of great importance to be able to construct it accurately, and to have a thorough knowledge of it. The relationship between concentration, temperature and any given property—electrical conductivity, specific volume, magnetism, &c.—was best and most clearly brought out by the employment of a co-ordinate system in three dimensions. Thus, taking concentration and temperature as the base, ordinates could be erected whose lengths were proportional to the numerical values of the property under consideration, and so a series of intersecting curved surfaces could be obtained, each of which corresponded to a particular phase-region of the equilibrium diagram. The converse problem, *viz.*, that of obtaining the equilibrium diagram (when it was unknown) by projection from these surfaces on to the basal plane, was one of great importance. The best known method and one which had been hitherto and was still most universally employed for the determination of the equilibrium diagram was that known by the name of "thermal analysis," in which special account was taken of the variations in the "total heat" of the systems under consideration. The author discussed at length the limitations of "thermal analysis," and in particular explained why it failed in those cases where, as so often happens in practice, a state of complete stable equilibrium was unattainable within a comparatively short interval of time. The respective merits of electrical conductivity and of specific resistance measurements were set forth and illustrated by numerous examples from practice.

Current Topics.

Subjects of current interest dealt with in this issue include the following:—

Mr. J. Rezelman contributes an article on "The Determination of Synchronous and Asynchronous Reactance."

Dr. R. A. Houstoun continues his series of "Studies in Light Production," considering this week "The Welsbach Mantle."

In an article entitled "Electric Tin Smelting" Mr. J. Hirlén describes what has recently been done in this direction in this country.

At the recent International Congress of the Applications of Electricity, at Turin, Prof. Silvanus P. Thompson presented a "Report on Motor-Generators, Converters and Rectifiers."

We give a complete account of the recent Turin meeting of the International Electrotechnical Commission.

We give a further instalment of Mr. T. F. Wall's British Association Paper on "The Single-Phase Repulsion Motor."

A volt-hour meter has been placed on the market by the British Westinghouse Electric & Mfg. Co. This enables engineers to keep a check on the average voltage of sections of their systems.

A digest of the revised scheme of examination for inspectors of mines is given in another column.

An abstract of the Board of Trade Report on Strikes and Lock-outs and on Conciliation and Arbitration Boards in 1910 is given in another column.

The Municipal Tramways Association has been registered, but the word "Limited" is omitted from the title by licence of the Board of Trade.

What seems like a boom in church lighting is in progress in many parts of the country. In the Stoke Newington (London) district four churches have been "converted" during the past three months.

At their meeting last week Shoreditch (London) Council approved the scheme for the extension of incandescent electric lighting to the portion of the borough north of Old-street. The southern portion is already illuminated by metal filament lamps.

We continue our account, in the "Industrial and Commercial Supplement," of the exhibits at Olympia. The need for greater publicity being given to the Exhibition is referred to in our Editorial Notes.

Companies' Meetings and Reports.—At the meeting of Cleveland & Durham Electric Power (Ltd.) on Tuesday the Chairman gave particulars of the progress of the Company, and announced that power contracts in hand amounted to 40,460 H.P.

The ordinary general meeting of Dick, Kerr & Co., held yesterday (Thursday), is reported in another column.

APPOINTMENTS VACANT AND FILLED.

Test-room assistants, for adjusting and calibrating a.c. and d.c. instruments, are wanted; also assistants for photometry. See advertisement.

A working electrician is required for large works plant, with experience of motor repairs and wiring for lights. See advertisement.

A shift engineer is wanted for a power house with h.t. a.c. and d.c. plant. Salary £2. 5s., rising to £2. 10s. per week. See advertisement.

Messrs. Harland & Wolff, engineers and shipbuilders, Belfast, advertise for an electrical wiring draughtsman.

Mr. Wilfred S. Peake has been appointed assistant to the expert in wireless telegraphy in H.M.S. "Vernon."

Mr. Hubert Dobell, an engineer in the service of Marconi's Wireless Telegraph Co. (and for some years attached to Mr. Marconi's personal staff), has been appointed chief of the radio-telegraph service of the Turkish Government. He will shortly return to England from Spain, before proceeding to Constantinople.

EDUCATIONAL NOTICES.

University of London, University College.—The calendar of the University College for the 1911-12 session has been issued. Full particulars of the courses of instruction provided by the College are given, and among many new developments the following may be noted:—

In the faculty of engineering the institution of a new lectureship in heating and ventilating engineering, and the appointment of Mr. Arthur Barker thereto. A full course of instruction in heating and ventilating engineering and a course of public lectures on "The Real Nature of the Problems in Heating and Ventilation awaiting solution by the Engineer"; and courses suitable for those who have completed a diploma or degree course in engineering, occupying the whole session, are arranged in several branches of engineering, and facilities for research are provided to suit the needs of individual students. Among the courses of special lectures are those by Mr. E. Kilburn Scott on "Electrical Design," by Mr. W. J. Goudie on "Steam Turbines," by Mr. H. Deans on "Railway Engineering," by Mr. W. C. Clinton on "Illumination and Photometry," by Mr. A. R. Low on "The Design and Calculation of Aeroplanes," by Mr. W. N. Blair on "Roads, Street Paving and Tramways," &c. The post-graduate and special courses of lectures at University College are carefully arranged, and are under the control of experts. The number admitted to each course will be limited, and applications for admission should be addressed to the Secretary (Mr. W. W. Seton, M.A.), Gower-street, W.C.

University of London, King's College.—Complete courses of study, extending over three or four years, are provided in civil, mechanical and electrical engineering for engineering degrees of the University of London, and for the diploma and certificate of the college.

The four-years' course provides, in addition to the academic training, opportunity for practical training in works. Special advanced lectures and courses in civil and mechanical as well as electrical engineering, will commence in October. Among the lecturers in electrical engineering are Mr. W. H. Patchell, who will deal with "Electric Generating Stations" and "The Application of Electric Power to Mines and Heavy Industries"; Mr. F. Lydall, who will lecture on "Electric Traction, Direct and Alternating Current"; and Mr. Wm. Brew, who will deal with "Electric Lighting." Detailed syllabus and further particulars may be obtained from the Secretary, King's College, Strand, London, W.C.

University of Edinburgh.—The next session opens on Oct. 10. The University provides complete courses in civil, mechanical and electrical engineering, qualifying for the degree of B.Sc. in engineering, and extending over a period of three years. Particulars from the Matriculation Office, The University, Edinburgh.

University of Durham.—Armstrong College, Newcastle-upon-Tyne.—Courses of instruction are provided in mechanical, marine, civil and electrical engineering, naval architecture, mining, metallurgy, agriculture, pure science, arts and letters. Particulars from the secretary, Mr. F. H. Pruen, M.A.

Northampton Polytechnic Institute, Clerkenwell, London.—The full day courses in the theory and practice of mechanical and electrical engineering and in electro-chemistry commence on Oct. 2. The courses in mechanical and electrical engineering include periods spent in commercial workshops, and extend over four years, and they also prepare for the degree of B.Sc. in engineering of the University of London. There are also full and partial day courses in technical optics. Particulars from the Principal, Dr. R. Mullineux Walmsley.

University of Bristol.—A pamphlet setting out the record of the occupations of former engineering students of the Merchant Venturers' Technical College and the late University College (Bristol), has been issued by the Faculty of Engineering. The list is compiled alphabetically, and contains records of over 350 students, many of whom occupy responsible positions.

Finsbury Technical College.—The evening classes in electrical engineering at the City and Guilds Technical College, Finsbury, begin on Oct. 2. Prof. S. P. Thompson will give a course on "Alternating-current Work" and on "Dynamo and Motor Design," and Mr. Simmons will give a few lectures on "Transmission and Distribution of Electrical Energy." On Wednesday evenings Prof. Thompson will deal with "Magnetism, and the Design of Commercial Magnets," and Mr. Howgrave-Graham with "Electric Measurement," with "Illumination," and the more elementary principles of dynamos, transformers, &c. Special courses of lectures on "The Calorimetry of Fuels" and on "Petrol Engines" have also been arranged.

In the mechanical engineering department Mr. G. K. B. Elphinstone will give an inaugural lecture on the "Gyrostatic Compass." The chair will be taken by Mr. S. W. Luard at 8 p.m. on Tuesday next, Oct. 3.

Borough Polytechnic Institute.—Day and evening courses of instruction are given at this Institute. In addition to the engineering, building and technical trades and science classes, provision is made for instruction in commercial subjects and languages, &c.

The physics and electrotechnics department is under the control of Mr. John Henderson, D.Sc., A.M.I.E.E. The lecture theatre can accommodate 100 students, and there are two large well-equipped laboratories for practical work. The courses of instruction in electrotechnology are arranged to cover a certain period of years. There are also advanced and honours courses in pure electricity, and a three-years' course for electric wiremen. During the past year the governors have spent large sums of money in decorating, extending and improving the accommodation of the Institute, and they are contemplating the establishment of a special school for the ironmongery and hardware trades. Particulars from the principal (Mr. C. T. Millis), 103, Borough-road, S.E.

University Correspondence College.—The September issue (No. 59) of the "Matriculation Directory," which is published (at 1s. nett) by the University Correspondence College, of Cambridge and London, contains much useful information for candidates for the matriculation and other examinations of the University of London. The articles on text-books and courses of instruction are written by experts. At the University Tutorial College (32, Red Lion-square, W.C.), which is affiliated to the Correspondence College, there are day and evening classes in preparation for examinations of the University.

ARRANGEMENTS FOR THE WEEK.

FRIDAY, September 29th (To-day.)

MUNICIPAL TRAMWAYS ASSOCIATION.

11 a.m. Excursion to Ayr and the Land of Burns, arriving back at Glasgow at 7:20 p.m.

MONDAY, October 2nd.

SOCIETY OF ENGINEERS.

7:30 p.m. Meeting at the Institution of Electrical Engineers, Victoria Embankment, W.C. Paper on "The Necessity for Safer, Quicker and Cheaper Railways, with Some Proposals Therefor," by Mr. C. R. Enock.

TUESDAY, October 3rd.

FARADAY SOCIETY.

8 p.m. Meeting at the Institution of Electrical Engineers, Victoria-Embankment. Papers on the "Paragon Electric Furnace and Recent Developments in Metallurgy," by Mr. J. Härdén; "Progress in the Electrometallurgy of Iron and Steel," by Mr. D. F. Campbell; and on "The Hering 'Pinch Effect' Furnace," by Mr. E. K. Scott.

THURSDAY, October 5th.

IRON AND STEEL INSTITUTE.

10:30 a.m. Meeting at the Institution of Civil Engineers, Great George-street, Westminster. A selection of Papers will be read and discussed. If necessary the meeting will be resumed in the afternoon.

THE LONDON ELECTRICAL ENGINEERS.

Officer Commanding, Col. H. M. Leaf.

The following orders have been issued:—

Drills for efficiency (1911-1912) will commence at head-quarters on Thursday, November 2, 1911, and head-quarters will be open as follows from that date: Daily (except Saturdays), 10 a.m. to 10 p.m. Saturdays (unless otherwise ordered), 10 a.m. to 12 noon.

THE USE OF ELECTRIC LOCOMOTIVES FOR SHUNTING PURPOSES.*

BY ALBERT H. MARSHALL.

The object of this Paper is to direct attention to an important commercial application of electric power which, in the author's opinion, has not received the consideration and adoption it deserves. Shunting is taken to include: (1) The handling of heavy goods and mineral traffic in yards and sidings as now done by steam locomotives; (2) the haulage of minerals below ground as now done by stationary engines and horses—with particular reference to the Cleveland Iron Stone Mines.

The matter being one of costs and not of revenue—and the haulage costs being in most cases but a small portion of the total works cost—is probably the real explanation why the subject has not received more attention. There are, however, other reasons which may be advanced, such as the general objection to bare electrical conductors, difficulty as regards interchangeability of traffic, and the natural disinclination which usually exists to disturb a condition of things by which reasonably good practical results are obtained.

Shunting by steam locomotives differs from the rest of railway work in that the running costs of this particular work are relatively very much higher than those of other railway service; the shunting costs under electrical operation on the other hand should not be materially higher, and may even be somewhat lower than those of other kinds of work. The extent to which a saving in this respect is possible does not seem to be generally appreciated. Underground haulage by horses, and, in some cases, by cable, are also expensive modes of traction, and here again large savings can be effected.

The author will show that electric locomotives can be used with advantage for most shunting operations, and that it would be sound commercial policy to substitute them for the existing locomotives, horses and cable haulages.

Choice of System.—Speaking generally, the single-phase system only shows to advantage for long-distance main-line traffic, which will probably not be dealt with in the first instance; on the other hand, there is every inducement to railway companies at once to electrify their suburban services, for which the continuous-current system is cheaper and more suitable. It would seem, therefore, that commercial and practical reasons will lead to the continuous-current system being generally adopted.

A short discussion of the merits of the various electrical systems is given in an appendix, in which the author hopes he shows good reasons for his advocacy of the continuous-current system for the class of work under consideration.

Although "shunting" covers a very wide field, it is possible to draw up a general specification for a standard type of equipment capable of meeting all demands likely to be made on it. This specification would in brief be somewhat as follows:—

System.—Continuous current; 550 volt; negative side earthed; track rails as negative conductor.

Motors.—Series wound; 1, 2 or 4 per locomotive.

Control.—Series parallel with resistances.

Collector Gear.—Single overhead conductor with bows or trolleys. Provision for third-rail gear. For underground haulages, however, a lower voltage, say 250, would be safer, and where exposed conductors are inadmissible, the use of accumulator locomotives is suggested. These exceptions are dealt with under the section devoted to mining conditions.

Locomotives.—Typical electric locomotives are illustrated in the Paper, and the features of electric, as compared with steam, locomotives discussed. The power that can be got out of a steam locomotive depends upon the state of the boiler, the skill of the fireman and the quality of coal used; with electricity, so long as the voltage of the line is maintained and the motors are in any sort of running condition, the locomotive can always be relied upon to develop its rated horse-power. From the point of view of adhesion or grip of the driving wheels on the track rails, the electric motor has an advantage over the steam engine in that the torque exerted is quite uniform; for this reason there is not the same tendency to slip when starting under load. In the calculations herewith the adhesion of the electric locomotive has been taken at 0·235 and that of the steam locomotive at 85 per cent. of this figure, or 0·20. This effect is counterbalanced in practice owing to the steam locomotive being for other reasons made heavier than an electric locomotive of the same drawbar pull, but only at the cost of the power necessary to move the additional weight.

As regards ability to perform useful work, the electric locomotive has a distinct advantage over the steam locomotive in the following respects: (1) It loses no time on the road, coaling, watering, boiler tending and waiting for steam pressure to rise; (2) it accelerates more quickly and is more easily controlled; (3) it requires no shed day for boiler cleaning, &c.; (4) it needs fewer repairs and renewals. The first two points mean that more work can be done per loco per day, and the second two that fewer spare engines are necessary for the same service; the first two affect the wages question and all of them have to be taken into consideration in settling the proportion of electric to steam locomotives required for a given service.

The exact amount of time that can be saved in carrying out a series of operations is difficult to determine, as it depends a great deal on the class of work to be dealt with. In the case of shunting in a busy blast furnace yard (particulars of which are given) the average running speed of the engine was found to be a trifle over 4 miles per hour; the distance travelled per shift from 16 to 20 miles, and the percentage of standing time to running time over 50 per cent. If now, which does not seem unreasonable, the traffic arrangements could be improved to permit of the running time being lengthened by only 10 per cent., and of the average speed being raised from 4 to 4½ miles an hour, then four engines would do the work of five. This is a much lower estimate than that generally given in comparing the relative capacities of steam and electric locomotives, but it is the conservative one which will be taken in this discussion.

As regards spares, one engine over and above every 10 engines daily in commission should be an ample allowance; below 10 and above three a spare should also be provided; for three and under it would probably be sufficient to carry a stock of spare parts.

To facilitate a determination of the size of locomotive required for any particular duty, the author gives a number of tables showing how steam and electric locomotives compare as regards weight, tractive effort, cost and other essential features, based on equal brake-horse-power outputs for one hour. Some of the figures are summarised in Table I. herewith.

Table I.

B.H.P. rating.....	90		150		390	
Speed	6 m.p.h.		6 m.p.h.		9 m.p.h.	
	Steam. Tons.	Elec. Tons.	Steam. Tons.	Elec. Tons.	Steam. Tons.	Elec. Tons.
Total weight loaded	12·0	10·0	26·0	22·0	61·0	55·0
Available tractive effort	2·4	2·4	5·2	5·2	9·6	12·9
Approx. price.....	£700	£650	£1,200	£1,100	£2,250	£2,100

The steam engine designer is confronted with a serious problem when he has to produce an engine of more than about 26 tons. Up to this weight, the load can very well be carried on two axles; above that weight he has to add one or more axles in order to keep his axle load within limits and to carry the extended boiler necessary to supply the additional steam required. These axles have to be coupled together so as to make the total weight available for adhesion, thus increasing the rigid base from 6 ft. to 12 ft. or more. In heavier engines requiring greater fuel capacity, the framing has to be lengthened to provide sufficient coal and water accommodation, necessitating the use of a small bogie truck, or some form of radial axle to carry the extended portion. The weight so carried is not available for adhesion and in the tank engine corresponds in this respect to the tender which main-line goods locomotives have to drag after them. In the electric locomotive each axle is independently driven, and sizes up to 60 tons or thereabouts can be built with a rigid wheel-base not exceeding 6 ft., the whole of the engine weight being available for adhesion. The weight which has to be added for adhesion in the case of electric locomotives can be made use of in a variety of ways. For instance, a locomotive of full shunting capacity could be fitted with a crane capable of lifting heavier loads than the usual pattern of yard crane, thus saving in many cases the cost of a second machine and shift of men; it could be provided with a hopper for carrying paying load, or be adapted for other purposes of transportation.

Line and Track Equipment.—Except in some few special cases, the locomotives can be best supplied with power by means of overhead conductors, the track rails being used to complete the electrical circuit in accordance with standard tramway practice.

It is desirable to obtain as much headroom as possible in yards where locomotive cranes have to operate, but apart from the restriction imposed by the use of this type of crane, there appears to be no necessity to suspend the wires at a greater normal height than 16 ft. As, however, provision should in most cases be made for the use of cranes, it has been thought better to settle on a uniform height of 22 ft.

On sidings belonging to the North-Eastern Railway at Newcastle, the Harton Collieries and the Newcastle-upon-Tyne Electric Supply Co., 16 ft. or less has been considered sufficient. An increased height of trolley wire means an increased cost of the overhead structure, as the supports have not only to be lengthened but to be made corre

* Includes oil, coal and water.

spondingly stouter; in addition, the collector gear on the locomotive becomes more expensive.

As regards the method of suspension, there is no need with the low speeds incidental to shunting work to adopt an expensive construction. The ordinary span-wire construction with the conductor approximately in the middle of the track permits the use of the reversible type of bow collector and is quite satisfactory for the purpose.

Even with a 22 ft. height of trolley wire, there would still be trouble due to the fouling of the wires by the booms of long jib cranes such as are commonly used, and it therefore seems advisable to change the type of crane, using one with a fixed instead of movable boom. In this way a safe clearance can be got.

In equipping the yards and sidings of blast furnaces and steel works for successful electrical operation, the author realises that here and there difficulties have to be met, but these are not of a serious character, and are such as can be successfully overcome. Probably the most real difficulty is found in dealing with the jib type of crane. If, however, as suggested above, the solution lies in providing new cranes, advantage can be taken of the change to substitute electrical driving for steam, and so to effect a saving in operation proportionate to that obtained by the main conversion.

Wherever existing overhead wires interfered with the locomotive conductors, or an alteration in their position became desirable for the purpose of safety, they could be conveniently carried on extensions of the trolley wire supports.

Running Costs.—Table II. gives in detail the actual costs of shunting by means of steam locomotives at several works in this district.

Fuel Consumption.—By means of electricity, instead of a number of comparatively small and wasteful prime movers, energy can be obtained in a more advantageous manner from a few large and efficient machines in a central power station, whilst the supply of a number of varying loads from large machines improves the load factor.

The author illustrates this argument by particulars of a series of careful tests extending over several days taken on seven shunting engines at Newport Works. The following is a summary of the results obtained:—

Average gross load, including engine weight, 60·5 tons.
Average net load carried, 16 tons.
Average running speed, 4·09 miles per hour.
Percentage of total time running, 49 per cent.
Average miles run per shift, 17 miles.

He shows that if a power station were put down to deal with the service performed by these seven locomotives, one engine of a capacity less than that of three of them, running under much more efficient conditions, and fed from boilers using a cheaper quality of coal, would meet the requirements of the case. The saving effected thereby might be more than sufficient to cover the losses in converting from mechanical to electrical energy, transmitting from power house to locomotive, and converting back again. Moreover, advantage could be taken of the existence of the central station to supply power for other purposes, and thus to improve the load factor and decrease the capital charges. In the majority of cases, probably, the same end would be attained by driving the electric locomotives from a power station already in existence. Again, to pursue this policy to its logical conclusion, a greater saving can invariably be made by purchasing electrical energy from a large power supply company where such exists.

The author has not been able to discover any recorded results of the performance of steam shunting locomotives given in a form that admits of a fair comparison with what can be done by any other kind of motive power. He, however, compares the fuel costs of a non-condensing locomotive engine with the performance of a medium-sized turbo-generator, and then discusses the consumption of electrical energy per ton-mile and analyses it into its various constituents, a number of diagrams being given in this connection.

Repairs and Renewals.—Compared with street-tramway conditions, shunting conditions are less hard on the electrical equipment, as the motors, being further removed from the ground, are not exposed to the same extent to mud and wet; neither, as regards comparison with heavy suburban railway services, do the motors and other parts get covered with brake dust, which on underground railways especially is found to be a source of trouble. Judging from the very extensive experience derived from the use of similar electrical apparatus in other fields, it should be perfectly satisfactory for the work under consideration.

From a review of figures stated by Mr. Aspinall, Mr. Joshua Shaw and Mr. F. W. Carter it can be stated with some assurance that the maintenance of electric locomotives used for shunting work should not exceed from £20 to £50 per annum; also £30 per annum has been taken as an average figure to cover the cost of line and track equipment maintenance per single-track mile.

That electrical operation for this class of work has a beneficial effect on the life of the track rails is unquestionable; the ability of the electric locomotive, with its shorter wheel base, to negotiate sharp curves, reduces the wear and tear on points and crossings, while its lower rolling weight per axle is generally of advantage to the permanent way. Its better starting torque also reduces slipping at the driving wheels when starting under load.

Superintendence and Wages.—As regards superintendence the charges now allocated to steam locomotive operation will not be materially altered; much less supervision is required to keep an equivalent number of electric locomotives in working order, but, on the other hand, there is a responsibility for the maintenance of the overhead and track equipment to be assumed by someone.

The amount to be paid annually in wages for driving the electric locomotives should be somewhat reduced compared with the cost of driving a number of steam locomotives performing the same service, owing to the duties being very simple; moreover, as shown above, four electric locomotives could be taken as the equal of five steam locomotives (there would thus be a saving of one shift of men for every five steam locomotives displaced).

Comparative Estimates.—Taking the seven cases set out in Table II., the author next gives in a table a comparison of the operation of the shunting work in question by electric locomotives.

The cost per ton-mile and the annual saving by electrification for the seven cases considered are shown to be:—

A.	B.	C.	D.	E.	F.	G.
0·75d.	0·65d.	0·44d.	0·316d.	0·305d.	0·112d.	0·26d.
£413	£246	£202	£1,272	£2,454	£1,443	£3,887

Depreciation is allowed at the rate of 4 per cent. per annum on both the steam and electrical equipment, although the latter has perhaps some advantage in this respect. Interest at the rate of 5 per cent. per annum has also been charged on the cost of electrification, after deducting the scrap value of the steam locomotives.

Special Mining Conditions.—The great desideratum in mining is safety, and any system which on the whole tends to increase, in any

Digitized by Google

degree, the present risks is inadmissible. It may be taken for granted that the employment of electric accumulators would not introduce any new danger; on the contrary, traffic conditions in this respect would be improved, in that the driver has complete control over his work, and, by the light which can be readily provided, is better enabled to see what he is doing. Braking will be more efficient than with rope or horse haulage, resulting in fewer runaway tubs—a frequent source of accident in mines. The principal disadvantage of the accumulator method of traction is its cost, but this is permissible where horse haulage is the only alternative.

As regards the overhead trolley system, the restrictions practically limit its application to metalliferous mines where the seams are 9 ft. or more in thickness. In the Cleveland Iron Mines there is, as a rule, plenty of headroom and a sufficiently sound roof to which overhead conductors could be attached. Under such conditions there can be no objection to the use of bare conductors, provided the voltage does not exceed 250 and the work is carried out in a proper manner. The wire can, if thought necessary, be guarded by boards fixed alongside. One important advantage this system has is the facility which it offers for the complete lighting of the whole of the workings.

As regards locomotive capacity, an engine capable of drawing two loaded trucks up a grade of 1 in 14 at a speed of 3 miles per hour should be suitable except for the main roads. This specification can be met by an accumulator locomotive of convenient dimensions and weighing not more than 3½ tons. Built with 15 in. wheels and a wheel base of 2 ft. 9 in., it would operate quite well on a 2 ft. 6 in. gauge around the sharpest curves and over any track suitable for horse traffic. It could also be fitted with collector gear, which would enable it to run over any electrically equipped track and to replenish its batteries while doing so. A two-motor equipment of standard type is proposed, the regulation being "series parallel" with one controller. A form of hand brake capable of holding back any number of tubs on any grade up which the locomotive could pull them would be fitted. The accumulator battery has a capacity of 16 kw.-hours and is capable of discharging at the rate of 14 H.P. for one hour or of 7 H.P. for three hours. This capacity would enable it to handle 100 ton-miles per shift with a sufficient margin.

For roads equipped with trolley wires and over which there is a considerable traffic, a heavier engine, say one of 6 tons, could be used with advantage; this size, if provided with a motor capable of slipping its wheels, would easily start and haul a set of six loaded tubs up a grade of 1 in 20 at 4 or 5 miles per hour. With suitable motor capacity the draw-bar pull of any locomotive deriving its power direct from a central station is proportional to its weight, so that the size of engine required for any particular work can be readily determined.

The collector gear proposed consists of a trolley arm, identical with that used on street tramways, instead of the sliding bow attachment recommended for general yard shunting. There is not room for the latter underground, nor is the trolley at the same relative disadvantage that it would be for above-ground use, as it is within easy reach of the driver, and can thus be more readily controlled.

The insulated conductors would be suspended from the roof timbers or road-sides. Solid copper wire of 0·10 sq. in. section is suggested as a convenient size of conductor. With this section at 250 volts sufficient power could be economically transmitted a distance of from a mile to a mile and a quarter, radially, from any distribution point. Distribution points would be situated in-bye to suit the geographical formation of the mine, and be fed from high-tension three-phase distribution mains through small motor-generators. The high-tension mains could also be used to convey power for pumping and ventilation.

As regards costs, the author has been favoured with details of the existing costs at some of the Cleveland mines, and has been enabled to examine the working conditions at these mines. In one case, which will serve for the purpose of illustration, horse haulage involves an annual expenditure, when everything is included, of almost exactly £10,000 per annum. The output of stone is a little over half a million tons per annum, and the average length of haul about a quarter of a mile. The total ton-miles (inclusive of tare and empties) works out at 320,000 per annum, each horse doing on an average 16 ton-miles per shift. Estimating on a very moderate basis a locomotive should be able to do the work of two horses in collecting and distributing at the face, and of four horses in hauling along sidings and branch roads. Allowing a battery efficiency of 50 per cent. and 25 per cent. for the cost of battery maintenance, the total of the annual charges, including interest and depreciation on new capital, assuming the whole of the work to be done by accumulator locomotives, should not amount to over £6,200. With the trolley system in use along the secondary roads and accumulators only on the locomotives at the face, there would be a still greater saving.

The success of accumulator traction depends mainly upon the cost of battery renewals; if, as accumulator manufacturers claim, this will not, all things included, exceed 25 per cent. of the first cost per annum, then a strong case can be made out for accumulator locomotives. The weight of the battery is not for this purpose a disadvantage as weight has to be provided to get sufficient adhesion. In Germany a large number of accumulator engines are in use for mining work, and in the United States a remarkable degree of success has been obtained with accumulator vehicles, used as delivery vans and the like.

It is difficult to make a fair comparison between electric locomotive haulage and rope haulage, and the author has not had sufficient time at his disposal to deal properly with the matter. In general, however, rope haulage is fairly economical under steady loads on straight track; it cannot, however, handle fluctuating loads so well nor does it admit of extension to branch roads and sidings without greatly increased wear and tear on longer ropes, or the provision of additional winding gear.

The accumulator method of electrical propulsion will, no doubt, appeal more strongly to mines managers than the trolley system, and until some experience has been gained with locomotives of the former type and a further stage of development reached in electrical matters, it is unlikely that the overhead trolley system will come into general use, although it has met with a very extended application in American and German mines.

From a humane point of view there is also something to be said for mechanical as against horse haulage, and the removal of the latter should improve the sanitary conditions of the mines somewhat. Electrical operation has also an advantage in that it facilitates the lighting arrangements, and, further, there seems no good reason why, where locomotives are available, the miners should not ride to and from the face and so be saved a certain amount of time and exertion.

Examples of Electrical Shunting.—The North-Eastern Railway Co. have had two 56-ton locomotives in use at Newcastle handling their quayside goods traffic for the past six years. These engines are individually capable of starting a 150-ton train on a grade of 1 in 27 and of hauling it on this grade at 10 miles per hour; they operate on track part of which is fitted with third-rail and part with overhead wires.

The Harton Collieries have six locomotives in use and 7 miles of track electrified; two other locomotives and the equipment of 8 miles of additional track are on order.

The Newcastle-upon-Tyne Electric Supply Co. and the Cleveland & Durham Electric Power Co. have locomotives for coal and ash traffic at their principal power stations.

The Consett Iron Co. at their Chopwell Colliery operate electric locomotives over 2¼ miles of track, the maximum gradient of which is 1 in 24 and the average 1 in 47; the locomotives are 14 tons in weight and haul a train of 36 tubs on a 2 ft. 2 in. gauge.

The Oakbank Oil Co. at Mid-Calder have two 11-ton engines running on a 2 ft. 6 in. gauge track and hauling some 600 tons of shale per day a distance of 2 miles.

A considerable number of powerful accumulator locomotives are in use for shunting purposes on the Prussian and Belgian railways.

Summary.—Perhaps the most striking outcome of this investigation is the indication it gives of the very small amount of useful work performed by steam engines in shunting operations. For instance, in the case of the Newport Works, it can be readily shown that the equivalent of the full amount of useful work done by the seven steam locomotives during the busiest 24 hours of the week, including that required to move themselves about, can be given out by any one of the comparatively small generators (1,250 kw.) at the waste heat power stations at these same works in 20 minutes.

In addition to the saving on fuel, there is a further large saving in locomotive repairs and renewals. Perhaps as good a case has not been made out in this respect for electrical driving as on its merits it is entitled to. Then, again, as regards the ease of operation and simplicity, too much cannot be said in favour of the electrical machine. A further advantage of the electric locomotive is that the driver has a clear view of his work, fore and aft, and so can more readily avoid collision, and, what is more important, accident to workmen. At night, too, very much more work can be done by the aid of the powerful head lamps with which each engine is fitted, while the dangers incidental to shunting operations are reduced. There is also something to be gained by reducing the output of smoke and steam in busy yards and thickly populated districts.

Large Hydro-Electric Plant in Brazil.—According to the "Electrical Review and Western Electrician" a contract has been let for the exploitation of the Paulo Alfonso Falls on the River San Francisco. At first 200,000 kw. will be developed, though the final capacity of the plant will be 1,000,000 kw.

THE DETERMINATION OF SYNCHRONOUS AND ASYNCHRONOUS REACTANCE.

BY J. REZELMAN.

Summary.—The action of the rotor of a synchronous alternator with respect to the stator is, in part, of a single phase and, in part, of a polyphase nature. The article deals with the reactance under various conditions of speed, &c., of the various possible combinations of single and polyphase stators and rotors; the polyphase stator with single-phase rotor is in particular interesting. Machines with non-salient poles only are considered.

Introduction.—In every alternating-current electrical installation there are, in addition to the main currents of normal frequency, supplementary currents of the same frequency and others. Supplementary currents of *normal* frequency are produced between synchronous machines:

1. By over or under excitation of the one relatively to the other,
2. By a difference in the irregularity of their speeds.

The circulating currents of *higher* frequency are due to harmonics in the E.M.F. curves, or to disturbances on the system produced by variation in the load, short circuit, &c.

For the currents of *normal* frequency the total *synchronous* reactance, direct and transversal, must be considered, and for the currents of higher frequency the total *asynchronous* impedance.

Generalities.—It is true that the rotor of a synchronous alternator has a single phase winding; yet owing to the presence of masses of metal forming secondary circuits, its action with respect to the stator is of the nature part single, part polyphase, or mixed (that is to say, a mean between the two).

Let us establish the approximate diagrams of such a machine with non-salient poles, acting as an induction, that is to say, an asynchronous motor.

Let

E_o = voltage per phase applied to stator,
R_δ = reactance of main magnetic circuit,
R_s = reactance of magnetic leakage circuit of stator,
$R_o = R_\delta + R_s$,
R_r = reactance of magnetic leakage circuit of rotor, in terms of the stator,
$R_{cc} = R_s + R_r$,
I_m = magnetising current,
I_o = light load current,
I_{cc} = current on short-circuit,
I_s = stator current,
I_r = rotor current.

A. Stator *polyphase*, rotor *polyphase*.—At synchronism the current on light load is

$$I_o = I_m = E_o/(R_\delta + R_s) = E_o/R_o,$$

and at standstill the short-current is

$$I_{cc} = E_o/(R_s + R_r) = E_o/R_{cc}.$$

For an intermediate speed it is known that the primary current I_s, with its lag ϕ, is determined by the circle diagram I_{cc} (Fig. 1) (the resistance of the windings is assumed to be negligible).

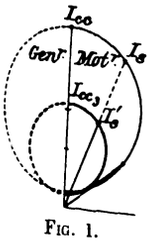

FIG. 1.

When the rotor is driven round in the direction of the rotating field at a speed above synchronism, the stator acts as a generator, following the continuation of the circle; and when the rotor is driven round in the *opposite* direction to the rotating field, the machine acts as a choking coil, the reactance of which is *constant*, independent of the speed, and equal to R_{cc}. The total impedance has then the limiting values of R_o and R_{cc}.

1. By placing an ohmic resistance r_s in series with the stator the current on light load becomes

$$I_{o_1} = E_o/\sqrt{R_o^2 + r_s^2},$$

and the short circuit current

$$I_{cc_1} = E_o/\sqrt{R_{cc}^2 + r_s^2};$$

however, the primary current I_{s_1} still follows the primitive circle I_{cc}.

2. By introducing an ohmic resistance r_r (reduced in terms of the stator winding) into the rotor circuit, the light-load current is not altered:—

$$I_{o_2} = I_o = E_o/R_o,$$

and the current on short circuit takes, as above, the value,

$$I_{cc_2} = I_{cc_1} = E_o/\sqrt{R_{cc}^2 + r_r^2};$$

the primary current still follows the same circle.

3. By placing a choking coil of reactance, R'_s, in series with the stator, the light load current becomes

$$I_{o_3} = E_o/(R_o + R'_s),$$

and the current on short circuit

$$I_{cc_3} = E_o/(R_{cc} + R'_s).$$

The primary current with its lag ϕ_3 is determined in the same manner, but by the circle I_{cc_3} (Fig. 1). The diagram is the same as if the supplementary reactance were part of the reactance of the stator winding itself.

4. By introducing a reactance into the rotor circuit, the light load current retains its value,

$$I_{o_4} = I_o = E_o/R_o,$$

and the short circuit current takes, as above, the value

$$I_{cc_4} = E_o/(R_{cc} + R'_r) = I_{cc_3},$$

when R'_r, reduced in terms of the stator winding, is equal to R'_s.

The light load current is then a little higher; otherwise the diagram is identical with the preceding one with the choking coil connected in the stator circuit.

B. Stator *single-phase*, rotor *polyphase*.—From the above it follows that to demonstrate that the circle diagram holds for this machine, it is simply necessary to show that the single-phase motor with polyphase rotor acts in reality as a polyphase motor with *a choking coil in series with the stator*.

To effect this we replace the single-phase winding by two equal polyphase windings, connected in series but in opposite directions. The current having the same intensity in the two windings at every instant, two rotating M.M.F.s are produced equal in magnitude, but rotating in opposite directions. The two rotating fields which are set up act upon the rotor as an alternating field, and their combined action will be the same since the resultant field attains the same maximum value. To obtain this equality let us see how the winding of such a machine can be realised.

(*a*) Take the case of a stator with r slots per pole, of which $r/2$ slots are wound single phase with s_n conductors; when a current of R.M.S. value I_s is passed through the winding the maximum value of the M.M.F. produced will be

$$= \frac{r}{2} \times s_n \times I_s \sqrt{2}.$$

Replace this single-phase winding by two two-phase windings, in which each of the r slots per pole contains s'_n conductors per winding ($2s'_n$ conductors per slot).

(*b*) In connecting the phases of the windings occupying the *same* slots in series, the *first* will be connected in the same sense, the others in the opposite sense.

The maximum value of the M.M.F. produced will be

$$2 \times \frac{r}{2} s'_n I_s \sqrt{2} = r s'_n I_s \sqrt{2}.$$

To obtain the same action it is necessary that $s'_n = \frac{1}{2}$ of s_n; in fact the M.M.F.s of the opposed phases counteract each other directly, and the other two remaining phases constitute quite simply a single phase winding identical to (*a*).

(*c*) By connecting the displaced phases in series, the maximum value of the M.M.F. produced will be

$$\sqrt{2} \times \frac{r}{2} s'_n I_s \sqrt{2}.$$

To obtain the same action it is necessary here that $s'_n = \frac{s_n}{\sqrt{2}}$.

Digitized by Google

Let us verify the E.M.F.s produced, the resulting flux having the same value Φ in the three cases:

(*a*) $E_o = K \times \frac{r}{2} \times s_n \times c \times \Phi \times 10^{-8}$.

(*c*) $E'_o = \sqrt{2}K' \times \frac{r}{2} \times s'_n \times c \times \frac{\Phi}{2} \times 10^{-8}$,

per phase

$= K' \times r \times s'_n \times c \times \frac{\Phi\sqrt{2}}{4} \times 10^{-8}$.

The volt-amperes absorbed will be:

(*a*) $E_o I_s = K \times \frac{r}{2} \times s_n \times c \times \Phi \times 10^{-8} \times I_s$,

(*c*) $2E'_o I_s = 2 \times K' \times r \times s'_n \times c \times \Phi \times \frac{\sqrt{2}}{4} \times 10^{-8} \times I_s$.

In order that the V.A. shall be the same it is necessary that

$$K \times \frac{r}{2} \times s_n \times c \times \Phi \times 10^{-8} I_s = 2K' \times r \times s'_n \times c \times \Phi \times \frac{\sqrt{2}}{4} \times 10^{-8} I_s.$$

and since $K = K'$, it follows that $\frac{s_n}{2} = \frac{s'_n}{\sqrt{2}}$, whence $s'_n = \frac{s_n}{\sqrt{2}}$ as obtained above.

It follows that the reactance *per phase* of the main magnetic circuit of the two windings in series will be one-half of that of the single-phase winding. To have the same reactance it is necessary to employ $\sqrt{2} \times s'_n = s_n$ conductors per slot, and to apply a voltage per phase equal to $E'_o \sqrt{2} = E_o$ = that of the single-phase winding.

Thus the reactance per phase of *each* of the two windings is then one-half of that of the single-phase winding.

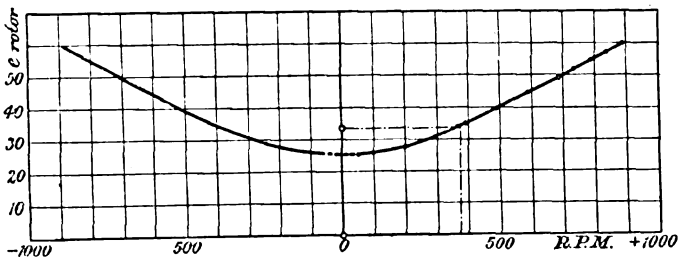

FIG. 2.—175 H.P. MOTOR, 3,000 VOLTS, 50 ∿, 750 REVS. PER MIN., WITH ROTOR OPEN.

Voltage between rings on rotor, the stator being magnetised single-phase, two phases in series, pressure being 250 volts. 25 ∿.

It follows from reasonings (*b*) and (*c*) that a single-phase winding can be replaced by two two-phase windings connected in series, the reactance per phase of the two windings in series being the same as that of the single-phase winding.

Let us now determine how this machine with the special equivalent winding operates. Assume the rotor to be open-circuited and driven at the speed of synchronism $+v_1$ it rotates then in the same sense as the one field and in the opposite sense to the other.

The field which rotates with the velocity $+v$ does not produce any induction in it, but the one rotating with the speed $-v$ produces an E.M.F. corresponding to the relative speed of $2v$, and hence of frequency equal to twice the normal (Fig. 2).

When the rotor circuit is closed, the latter, together with the winding I of the stator, constitutes a polyphase motor the rotor of which rotates at synchronous speed, and with winding II it constitutes a polyphase motor the primary field of which rotates in the opposite direction to the rotor.

At standstill, I and II both represent a polyphase motor on short circuit (rotor fixed).

It follows then, that I operates as a polyphase motor between the limits $+v$ and 0, whilst II is only a simply choking coil with constant reactance.

The windings I and II being connected in series, we can say that the *single-phase* motor acts like a *polyphase* motor having a *choking coil* in *series* with the stator.

By denoting the various reactances corresponding to each of the windings by $\frac{R_o}{2}$, $\frac{R_s}{2}$ and $\frac{R_r}{2}$ we have,

1. For the magnetising current,

$$I_m = \frac{E_o}{2(R/2)} = \frac{E_o}{R_o},$$

the voltage for each one of the windings in series will be $\frac{E_o}{2}$.

2. For the current on light load

$$I_o = E_o / \left(\frac{R_o}{2} + \frac{R_s}{2} + \frac{R_r}{2}\right) = E_o / \left(\frac{R_o}{2} + \frac{R_{cc}}{2}\right),$$

the voltage across I will be $I_o \times \frac{R_o}{2}$ and across II it will be $I_o \times \frac{R_{cc}}{2}$.

3. For the current on short circuit,

$$I_{cc} = E_o/2\left(\frac{R_s}{2} + \frac{R_r}{2}\right) = E_o/R_{cc}$$

the voltage for each phase will again be the same, *i.e.*, $\frac{E_o}{2}$.

The rotor constitutes a common secondary to the windings I and II; I induces a current I_{r_I} in it, displaced with respect to the primary current and varying in amount according to the circle diagram; II induces a current $I_{r_{II}}$, proportional and opposed to the primary current.

The resulting current in the rotor is $I_r = \sqrt{I_{r_I}^2 + I_{r_{II}}^2}$. Since I_{r_I} and $I_{r_{II}}$ are of different frequencies.

This explains at once the reason that the slip of a single-phase motor is not, as with a polyphase motor, determined by the total losses in the rotor; it is only the losses corresponding to $I_{r_1}^2$ which come into consideration.

(C) Stator *polyphase*, rotor *single phase*.—By replacing, as in the preceding paragraph, the single-phase winding of the rotor by two polyphase windings, we find in a fairly simple manner that the fundamental diagram of this machine is still a circle.

Consider what takes place at various speeds.

(*a*) *On light load at speed v.*—The rotor rotates in synchronism with the primary field, hence there is no E.M.F. produced in its windings; the stator consumes the light load current

$$I_o = I_m = E_o/R_o.$$

(*b*) *On load with a speed v, taken between v and* $\frac{v}{2}$.—The rotor slips relatively to the primary field, there is thus an E.M.F. and corresponding currents produced in its windings having a frequency $\sim_1$. The currents in winding I produce a field rotating in respect to, and in the same direction as the rotor, the actual speed being $v \times \frac{\sim - \sim_1}{\sim} + v \times \frac{\sim_1}{\sim} = v$ = constant, that is to say, the same speed as the primary field with respect to the stator.

The currents in the winding II produce a field which rotates relatively to the rotor, but in an opposite direction to it; this field thus rotates at a speed of $v \times \frac{\sim - \sim_1}{\sim} - v \times \frac{\sim_1}{\sim} = v\left(1 - \frac{2 \sim_1}{\sim}\right)$ relatively to the stator.

Since the speed of field II with respect to the stator decreases twice as quickly as the slip of the rotor, the field will be zero in space at half speed $v/2$. Below this speed the field II will rotate in a negative direction with respect to the stator. While the speed of the rotor varies from v to $v/2$, the frequency of the E.M.F.s induced by field II in the stator windings will vary from $\sim$ to 0, and for speeds from $v/2$ to 0 the frequency of the E.M.F.s will increase again from 0 to $\sim$. These E.M.F.s produce currents in the stator windings which complete their circuits by means of the distributing network.

The combined value of the ohmic resistance and reactance of the generators and motors operating in parallel across the mains is in general negligible in comparison with that of the motor; we can then consider that the stator winding constitutes a short-circuited secondary, so far as the rotor winding is concerned.*

* This depends upon the importance of the motor relatively to the network.

Digitized by Google

We therefore conclude that the machine with polyphase stator and single phase rotor is similar in action to two polyphase motors, the rotors of which, fixed to the same shaft, are coupled in cascade in such a manner that the field of I rotates in the opposite direction to that of II (Fig. 3).

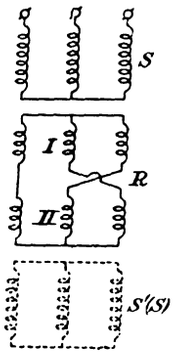

FIG. 3.

The table below shows the frequencies of the currents produced in the stator and rotor at various speeds.

Slip of the rotor R with respect to the primary field the stator S, per cent.	Frequency of the current produced in windings I and II of the rotor.	Frequency of the current produced by rotor winding II in the winding S (S') of the stator.	Electrical slip of the stator winding S (S') with respect to the field of the rotor winding II, per cent.	
10	5	40	800	
20	10	30	300	1
30	15	20	133	
33·3	16·65	16·65	100	
40	20	10	50	2
50	25	0	0	
60	30	10	33·3	
70	35	20	57	
80	40	30	75	3
90	45	40	89	
100	50	50	100	

The last column shows that the winding II of the rotor behaves:—

1. For a slip between 0 and 33·3 per cent. as a *choking coil.*
2. For a slip between 33·3 per cent. and 50 per cent. as an asynchronous *generator.*
3. For a slip between 50 per cent. and 100 per cent. as an asynchronous *motor.*

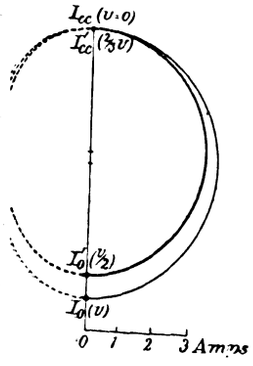

FIG. 4.

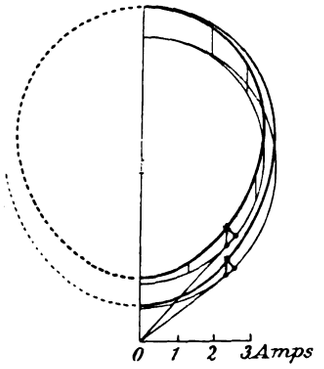

FIG. 5.

The rotor winding II constitutes for all slips from 0 to 100 per cent. the secondary of an asynchronous *motor*, of which the stator winding S is the primary: it follows then that the whole machine operates:—

Between v *and* $\frac{2v}{3}$, as a polyphase asynchronous *motor*, with reactance coil II in the *rotor* circuit.

Between $\frac{2v}{3}$ *and* $\frac{v}{2}$ as an asynchronous *generator* II, having *choking coil* S in series with the *stator.*

3. *Between* $\frac{v}{2}$ and 0, as an asynchronous motor II, having also a *choking coil* S in series with the *stator.*

In fact, it is well known that an asynchronous motor, with windings of small ohmic resistance, represents, for a slip well in excess of 33 per cent., a choking coil of approximately constant reactance of the same value as that of the motor at standstill.

It follows at once that for each of the three regions of speed 1, 2 and 3, the diagram will be a half-circle (Fig. 4).

The currents taken by the motor at the various characteristic speeds are:—

1. At speed v: $I_o = I_{cc} = E_o/R_o$.
2. At speed $\frac{2v}{3}$: $I'_{cc} = E_o/\left(R_s + R_r + \frac{R_r}{2} + \frac{R_s}{2}\right) = E_o/1{\cdot}5R_{cc}$.
3. At speed $\frac{v}{2}$: $I'_o = E_o/\left(R_s + R_r + \frac{R_o}{2} + \frac{R_r}{2} - \frac{R_s}{2}\right)$
$= E_o/\left(\frac{R_{cc}}{2} + \frac{R_o}{2} + R_r\right)$.
4. At speed 0: $I_{cc} = E_o/\left(R_s + R_r + \frac{R_r}{2} + \frac{R_s}{2}\right) = E_o/1{\cdot}5R_{cc}$.

The reactance of the first machine (stator with winding I of rotor as secondary) remains whole, whilst that of the second (winding II of the rotor with the stator as secondary) is halved. The current twice attains a maximum value I'_{cc} and I_{cc}. The voltages are composed as follows.

On the first machine.	On the second machine.
1. $I_o R_o = E_o$.	Zero.
2. $I'_{cc}(R_s + R_r) = I'_{cc} \times R_{cc} = \frac{2}{3}E_o$.	$I'_{cc}\left(\frac{R_r}{2} + \frac{R_s}{2}\right) = I'_{cc} \times \frac{R_{cc}}{2} = \frac{1}{3}E_o$.
3. $I'_o(R_s + R_r) = I'_o \times R_{cc}$.	$I'_o\left(\frac{R_o}{2} + \frac{R_r}{2} - \frac{R_s}{2}\right)$.
4. $I_{cc}(R_s + R_r) = I_{cc} \times R_{cc} = \frac{2}{3}E_o$.	$I_{cc}\left(\frac{R_r}{2} + \frac{R_s}{2}\right) = I_{cc} \times \frac{R_{cc}}{2} = \frac{1}{3}E_o$.

The stator winding constitutes at the same time the primary circuit of the first machine and the secondary circuit of the second: currents of different frequencies are therefore produced, and a hot wire ammeter will indicate the effective value of the resultant current, equal to the square root of the sum of the squares of the individual currents.

It is not the same with a wattmeter placed in the stator circuit; this indicates but little more than the power corresponding to the main watt current, since the voltage producing the secondary currents is very feeble.

It follows, therefore, that it is necessary to separate the two currents in order to find by experiment the real power factor of the main current. For this purpose it suffices to know that the secondary current produced in the stator is approximately one-half of the primary current; the main current is, therefore, $\frac{1}{\sqrt{1^2 + 0{\cdot}5^2}} = 0{\cdot}9 \times$ the current measured on test.

The circle diagram of the main currents is thus fixed by taking 0·9 of the limiting currents, that is to say, $0{\cdot}9 \times I_{cc}$ and $0{\cdot}9 \times I_o$. Similarly, the diagram of the resultant currents in the stator can be easily constructed from the fundamental circle; the diagram is then obtained in an oval form, as shown in Fig. 5.

It can readily be understood that the amperemeter should oscillate in the neighbourhood of synchronism at half and full speed, for then the frequency of the secondary currents in the stator is very small, corresponding to the slip. It should still further be remembered that ohmic resistance in the rotor completely alters the form of the diagram, the explanation of which can be seen above from paragraph A, sections (1) and (2).*

(To be concluded.)

* The analysis which we have just made also gives us all the elements necessary to establish the exact vector diagram; it is sufficient to consider the different regions of speed to obtain a continuous and complete diagram. We must be content with the above explanation without going at greater length into the matter.

ELECTRIC TIN SMELTING.

BY J. HÄRDÉN.

Summary.—Very little is known, outside a limited circle, of tin-smelting. The author, after describing the smelting of tin in the reverbatory furnace, gives particulars of an extensive series of tests he has carried out, using an electric process. This method offers considerable advantages; and he shows that it deserves consideration where electric power is cheap.

Very little has as yet been said or published on the subject of electric tin smelting: all that has been done so far in this respect seems to refer to the de-tinning of tin-plate. Occasional references to electric tin smelting may have appeared from time to time, but the writer has not been able to find any literature on the subject worth referring to, though this may be due to lack of opportunity.

Even the smelting of tin in the orthodox way—by means of the reverbatory or the shaft furnace—is but scantily mentioned in text-books, &c., and very little is generally known about tin metallurgy outside the circle of those directly interested in the subject. It may therefore be of interest to metallurgists to learn that electric tin-smelting was carried out on a large scale as a commercial experiment in Cornwall during last summer (1910) in a plant designed by the author, the Grondal Kjellin Co., of London, being consulting engineers.

A brief report is here given of the work carried out, together with a few general remarks on tin smelting; these remarks are, of course, not intended to cover the whole scope of the subject.

Cornish Tin Smelting.—Tin smelting in the reverbatory furnace has been carried out in Cornwall since time immemorial, and the metallurgy of that process is, in a broad sense, very simple, though to make it efficient requires a good deal of attention to minor technical details, and long practice. Broadly speaking, the method is this:—

The tin ore, chiefly consisting of tin oxide (SnO_2), as mined in Cornwall, is dressed in streams or on tables at the mines so as to contain about 63 to 64 per cent. of tin. The ore is delivered in bags of about 3 cwt. each, in the form of a dense, red-brown, moist powder, ground fairly fine, say about 15 to 20 mesh. After allowing the ore to dry for some little time, depending upon the moisture, which may vary from 7 to 15 per cent., it is mixed with the reducing agent, a low grade anthracite called "culm," which contains a considerable quantity of slaty clay or aluminium-magnesium silicate, &c.

The quantity of culm to be used depends to a certain extent upon the character of the ore. A single ore is rarely used; indeed, the proper blending of different ores is one of the principal factors in producing an efficient melt. Bolivian or Straits tin ore is very often mixed with Cornish ore. Generally, about 20 to 25 per cent. of culm is used; for the first charges no other flux is added. It is customary to build a furnace so as to take a charge of 3 to 4 tons of ore and about ¾ of a ton of culm, some of the culm acting as fuel. A quantity of the ore is mixed with culm in various proportions and melted in a test crucible of graphite so as to ascertain the best yield.

It is essential to conduct the smelt so that the temperature is raised gradually, especially if the ore is of a silicious nature, because if the temperature rises too briskly, tin silicate and silicides will be formed; these go into the slag directly, causing a great loss. Also volatilisation must be guarded against, as the metal is comparatively very volatile. In very modern plants a condensing chamber is used to recover the losses. The charge is frequently turned over with iron rakes, so as to ensure an even distribution of the heat. In some plants a quantity of scrap iron is added to the charge before the melt is finished in order to cause impurities to be taken up by the iron rich slag formed.

The melt is finished after 6 to 8 hours, when the taphole is opened and the metal and slag are run off together into a hemispherical cast-iron pan, which is often provided with a special heating arrangement. Each pan will hold 4 to 5 tons of metal. The slag floats on the surface of the metal and is run off in iron boxes to solidify.

The first slag is generally rather rich in tint: it may sometimes contain 14 to 16 per cent. of tin in various combinations. It is therefore frequently used as an admixture to a subsequent smelt, or may be treated separately for tin. The final slag is said to contain about 6 to 7 per cent. of tin, and is therefore sometimes smelted together with lead refuse for solder tin. In more recent plants, however, the slag contains only 2·5 to 3 per cent. of tin.

The crude tin as first obtained is cast into large ingots, and still contains a considerable quantity of impurities. These ingots are placed on the sole of the reverbatory furnace and re-melted at slow heat and low temperature; this is the so-called liquation process. The pure tin is thereby run off and the impurities remain behind, forming the so-called "hardhead," which mainly consists of an alloy of tin with sulphides and arsenides of iron. The percentage of tin varies somewhat, but is always considerable, and this "hardhead" is a source of trouble to the smelters. One of the objects of electric smelting was to try to eliminate, if possible, the formation of this undesirable "hardhead," which is so difficult to treat separately.

After the tin has been liquated it is collected in a large pan or refining pot, heated from underneath. This tin is usually about 96 to 98 per cent. pure and still contains impurities of arsenic, tin sub-oxides, &c. For further purification so-called "tossing" and "boiling" are employed. The former consists in scooping the hot metal in thin broad streams through the air, whereby the impurities are oxidised and will float on the top. The "boiling," which is more common, consists in immersing a raw piece of wood of large dimensions in the metal, vigorously stirring the latter. (Formerly it was believed that only wood from apple trees would serve the purpose.) A violent agitation sets in, oxidising the impurities. In modern plants dry steam and air are blown through the metal for the same purpose.

A small sample is ladled out from time to time and poured into the groove of the "test stone," a porous, white sandstone. The behaviour of the solidifying metal, together with the fracture of the notched bar and the special sound of the "tin crying," tell the skilled smelter of the purity of his metal. Indeed, this test is so reliable that an experienced smelter can tell within 0·2 per cent the degree of purity of the tin. Refined tin should have 99·6 to 99·8 per cent. of tin.

The refined tin is usually cast into 28 lb. ingots and branded with the trade mark, or else into strips 18 in. long and about ½ in. thick.

Electric Tin Smelting.—At a first glance it would seem that the electric furnace would not adapt itself very well for the smelting of tin ore, since the temperature of the electric furnace would appear to be unnecessarily high for the reduction, and even injurious. However, this assumption is quite erroneous. The reduction of stannous oxide by carbon requires a comparatively high temperature, especially if a good separation from impurities is to be effected. Besides, tin is readily volatile at this high temperature, and in a reverbatory furnace with its wide hearth, communicating directly with the smoke stack, or else in the tin-blast furnace where air is forced through the charge, this volatilised metal is almost altogether lost, if complicated condensing devices are not provided for.

All the above can to a large extent be avoided with the electric furnace, if properly designed. Another feature is that the formation of "hardhead" can be greatly reduced if the process is carefully conducted. Finally, if the cost of power is not too high, decided economy compared with the reverbatory furnace is quite possible, as the experiments have shown.

As to the loss of tin in the slag, it has been conclusively proved that one can so conduct this operation that slags containing only 0·25 per cent. of tin may be produced in one melt; but it appears to be more economical so to conduct the process that a richer slag containing, say, 14 to 16 per cent of tin may be produced, and to treat this richer slag while white hot in a second furnace, thereby considerably increasing the output.

Theoretical Yield.—If tin oxide, SnO_2, is reduced by means of carbon, we may assume the ideal equation

$$SnO_2 + C = Sn + CO_2,$$

but that at least two-thirds of the reaction at the outset takes place according to the equation

$$SnO_2 + 2C = Sn + 2CO.$$

This is substantiated by the fact that a considerable quantity of CO can be seen burning at the mouth of the furnace. A certain amount of the CO will naturally serve as a reducer when passing through the charge in the shaft, and it is of importance for reasons given previously by the author,* so to conduct the charge that the reaction set out in the second equation above is predominant, though it will hardly be possible to realise this to a greater extent than 50 per cent. Also the packing of the charge in the shaft, owing to the weight and small size of the particles of ore, will prevent this to a certain extent. We may therefore assume that under proper conditions, and after some hours' run, the reactions set out in the two equations above take place in equal proportions.

Heat Energy Required.—According to Thomsen and other investigators, 118 grammes of tin will yield 145,300 gramme calories by combustion into tin oxide. This amount of energy will therefore be required for liberating 118 grammes of metallic tin. On the other hand, the combustion of 12 grammes of carbon into CO_2 will yield 96,960 gramme calories; and 24 grammes of carbon into 2CO will give (in round figures) 58,000 gramme calories.

Assuming, therefore, that the reaction takes place according to the first equation, the metal would require 474 kw.-hours, and if according to the second equation 855 kw.-hours, for 1 ton of metallic

* *See* "Electrochemical and Metallurgical Industry," Vol. VII., No. p. 16.

Digitized by Google

Assuming an equal proportion of each reaction, we would therefore require 665 kw.-hours per ton of tin.

In addition to this, a certain amount of energy is required for heating up the charge to the temperature of reaction. No actual measurements of the temperature in the furnace were taken, but judging from the appearance of the slag and the metal tapped, it may be safe to assume that the average temperature of the whole interior of the reactive ozone was about 1,400 to 1,600°C.

Previous experiments have shown that to liquify one kilogramme of slag, such as that from the furnace, requires on the average 500 kg. calories, or about 0·6 kw.-hour. If we assume an average of 20 per cent. of slag from ore (naturally depending largely on the class of ore used) we would need 130 kw.-hours for the slag.

The radiation losses through the furnace walls, electrodes and water-jackets are naturally of such nature that no accurate figures can be obtained, but it seems safe to assume this loss to be equal to that in the slag, or 130 kw.-hours, while the escaping gases in the furnace used for our experiment, left the furnace mouth at a temperature of about 800°C. The losses through this source may therefore be set at about 150 kw.-hours for each ton of tin.

In summing up these items, we there find that in practice it should be possible to produce one ton of tin with an expenditure of power equal to :—

For the reaction	665	kw.-hours.
For slag	130	,,
For specific heat	65	,,
For radiation losses	130	,,
For losses through gases	150	,,
Total	1,140	kw.-hours.

In the experiments carried out, this theoretical figure was not obtainable, as the furnace was too small, and also for other reasons given below, but a very fair result was obtained.

Practical Tests.—At the request of Mr. A. F. Maclaren, of London, the author was asked to carry out some experiments on those lines late in 1909. Some difficulty was at first experienced in finding a suitable place for the preliminary trials on a laboratory scale, but early in 1910 Dr. Walmsley, of the Northampton Polytechnic Institute, courteously permitted the tests to be made in the Electrochemical Laboratory of the Institute. A furnace had been designed for 800 amperes and 50 volts alternating current, though only direct current of about 300 amperes and 100 volts was obtainable at the Institute. The direct current was particularly unsuitable for this class of work on account of the heating effect being greater at the positive electrode, which was fully borne out in the experiments. Also, electrolytic effects on the slag were to be reckoned with. In addition to this, the tests had to be carried out so as not to disturb the ordinary work of the laboratory; this naturally affected the results.

In spite of these difficulties, however, the following results were obtained. The furnace was built up in a manner somewhat resembling that designed by Harmet for iron-ore reduction. It was provided with a bottom chamber of magnesite bricks, rammed with calcined magnesite mortar, in the usual manner. A charging shaft rested on a vault or arch. The inner diameter of the hearth was about 5½ in. and the total height about 14 in. Two inclined carbon rods, about 2½ in. in diameter, were used as electrodes and reached into the centre of the hearth, about 2½ in. from the bottom. No cooling jackets were used, though they would have been of great assistance. The wear and tear of these electrodes, however, was so little, in spite of the primitive arrangement, that it could hardly be taken into account. This was also manifested during later experiments.

In a preliminary heat, on Jan. 27, 1910, the charge consisted of :—Tin ore (about 63 per cent. of tin) 20 lb., coke powder 5 lb., flux 5 lb. Of this only 12 lb. of ore was actually reduced, owing to lack of powder. Altogether about 40 kw.-hours were consumed, of which 15 were used for heating up, and 25 for the reduction proper. The melt yielded 5¼ lb. of pure bar tin and 1¼ lb. in the shape of shots, thus corresponding to about 85·5 per cent. yield from the ore. The slag was very irregular, as only one taphole was provided, so that some metallic tin remained in the slag. The power expenditure therefore amounted to about 4 kw.-hours per pound of metal or 8,960 kw.-hours per ton. As mentioned above, however, there was considerable loss of heat owing to the arrangement of the furnace.

In the next trial, the slag from the first melt was used as a flux. This proved to be a disadvantage, as it required a much higher temperature to be remelted and the taphole froze very readily. In a subsequent test, 16 lb. of ore were smelted, giving 6½ lb. of pure bar tin and 2⅓ lb. of shots, or a total of 9 lb. of metal, equal to about 90 per cent. of the metal in the ore. The maximum power taken was 8·4 kw., and the total duration of the melt was 2 hours. The total power consumption, including heating up, was 19·2 kw.-hours, that is, 2·15 kw.-hours per pound, or about 4,300 kw.-hours per ton of metal.

The tin obtained from the furnace proved to be well over 99 per cent. pure: it contained very little iron and no arsenic. The slag varied in appearance; if the run was smooth, it flowed freely and showed a greyish glassy lustre. Three average samples of this proper slag were analysed and found to contain an average 0·5 per cent. of tin. The stiff, black slag obtained in some melts contained, however, as much as 8 per cent. of tin. Thus, the best thermal efficiency obtained from this little furnace was about 25 per cent., while the metallurgical yield was as high as 90 per cent.

A test for electrolytic recovery of the tin in the slag was also made. Some slag and refuse containing an appreciable amount of metal was fused with soda (which may be carried out at once, while the slag is hot). The product was readily soluble in water and could be electrolysed direct, with iron plates as cathode. A good deposit of tin was obtained, though the efficiency was not very high. If, however, the oxide from the slag were converted into chloride of tin, the theoretical power consumption would be about 1,820 kw.-hour per ton of metal. Assuming an efficiency of, say, only 50 per cent., this recovery may be possible where the power price is low, with a rotating cathode and scrap tinplate as anode.

In view of the above promising metallurgical results, it was decided to carry on experiments on a very much larger scale, and on a commercial basis. A power supply of 100 kw. was secured and a suitable site acquired, where a galvanised iron building was erected, a tank for cooling water was built and every facility provided for a conclusive test.

Electrical Equipment.—Current was obtained from a Diesel engine plant, supplying power to a tin mine, and a condition was that no fluctuation should be caused which might endanger the regular working of the pumps in the mine. The supply was three-phase current at 50 cycles and 650–575 volts. A Berry three-phase oil-cooled transformer was installed, and was supplied at 660 volts on the primary side, in star connection, with only a lightning arrester and a main switch on the line. The secondary side, which was also connected in star, with earthed neutral, had four tappings, capable of giving either 30, 40, 50 or 60 volts. The terminals ended in copper 'bus-bars on a slate panel, provided with heavy copper screw plugs for obtaining the desired combinations. Each phase on the secondary side was provided with an ammeter, whilst a voltmeter with a change-over switch served for all three lines. The recording and indicating wattmeters were on the primary side.

The 'bus-bars were connected to the furnace electrodes by means of four flexible cables of suitable size, arranged so as to give the least possible induction. As, however, the current was as high as 4,000 amperes, a certain decrease in power factor was inevitable, the average power factor being about 0·90. During the whole test, no disturbance whatever was caused. The distance between the power house and the smelting plant was about 600 yds.

Furnace.—The furnace used was a shaft furnace of special design. Owing to pending patent applications a detailed description of this, as well as of the details of the actual smelting process employed, will have to be deferred to a later occasion when these matters have been settled. One of the principal features in an ordinary reverbatory tin furnace is that the metal, like mercury, will percolate into the lining and brickwork in large quantities and remain lodged there until the furnace is broken up. In a large plant with a number of furnaces this means the locking up of a considerable capital for a long period, which naturally is objectionable. This is successfully avoided in the new design of the electric furnace, where only a minimum quantity of metal is retained, all the metal being drawn off as soon as it is formed.

Three electrodes of carbon, 8 in. × 8 in. square and 4 ft. 6 in. long, cooled by water-jackets were used. The electrodes were supported by means of holders extending over half the electrodes, the holders being raised as the ends were worn off. The holders were suspended by means of flexible steel rope, and worm-gear winches permitted of fine adjustment.

No direct arc was allowed to form, as this caused a great variation of the yield and the working of the furnace. The charge formed a cone-shaped heap in the hearth, covering the reaction zone, permitting the electrodes to "burn free," forming a small space filled with incandescent gas round the ends, this acting as a resistance in which the reaction took place. This is, as is well known among furnace men, the only efficient way of working a furnace.

Arrangements were made to prevent the escape of volatilised metal; only about 0·5 per cent. or less of tin found its way out of the furnace. Tapholes on different levels were provided for drawing off the metal and slag separately. Sometimes the slaghole was frozen up with a hard slag crust, especially if the ore was rich in iron; all this went into the slag. In that case a small auxiliary electrode was used for

Digitized by Google

burning the taphole open again. This could be done very easily, although it must be admitted that an oxy-acetylene jet would be even more handy.

The Smelting Process.—At the start of each series of tests, which usually lasted 10 to 12 days (there is no reason why the furnace should not be worked for months at a time), the empty furnace was warmed for about 4 to 6 hours by means of a small wood and coke fire; this was done to prevent cracks in the brickwork. In subsequent melts, this could be almost entirely dispensed with, since the lining had properly set. A charge of about 14 kg. of culm for each 100 kg. of ore, depending somewhat on the nature of the ore, was gradually filled in, while a current at 60 volts and of about 1,000 amperes per phase was switched on. As soon as the reaction commenced, the pressure was lowered gradually to the working condition of 40 volts and 2,500 amperes. This pressure and current were steadily maintained during the whole run. Only in the case of certain ores was a pressure of 30 volts used.

The current fluctuated considerably at the beginning whilst the cold charge was being thrown in, but as soon as the electrode commenced to burn free the fluctuations ceased. Within half an hour after the first charge the first tapping of metal could take place, while the first slag was drawn off after the furnace had been working for a couple of hours. The appearance of the slag rendered it possible for the experienced eye to judge if the charge was of the right composition or not; if of a glass-like, dark brownish-green colour, and freely leaving the taphole, the charge was right; if sluggish and light brown, it had to be altered.

After a few hours' run, certain re-agents were added at regular intervals. This successfully prevented the formation of "hard-head," causing the sulphides and arsenides of iron to enter into the slag instead of alloying with the tin. The result was that the metal as it left the taphole of the furnace was about 98 per cent. pure, if the right blend of ore, not too much contaminated with impurities, was used. In one test, ordinary Bolivian ore, with only 49·5 per cent. tin and about 15 per cent. of iron was smelted for about 10 days and yielded over 92 per cent. finally, and on some days even 97 per cent., of the metallic tin from the ore. The liquid metal was collected in the usual way in large pots of wrought-iron, heated from underneath and at the sides. By means of an air-pump, air was blown into the metal through a perforated iron pipe, the metal then being ladled into a second tank to set properly. With this simple operation, a metal of 99·75 per cent. purity, and even higher, was obtained. This is well up to the commercial standard. The metal was then poured into ingots of about 28 lb. weight, branded and stored in the usual way.

Output, Power Consumption and Loss in Slag.—These three factors were found to be in close relation to each other. It was found that a slag containing as low as 0·25 per cent. of metallic tin could easily be produced, but to do this in one operation proved to be less economical at the price charged for electric energy. The output was only about 6 to 8 cwt. per day and the power consumption correspondingly high, or about 3,000 kw.-hour per ton of metal.

Going to the other extreme, the operation could be conducted so that a slag containing 17 to 19 per cent. of tin was produced. In that case, the output increased to 1 ton 11 cwt. per day, with a power consumption of 1,300 kw.-hours per ton of metal. As only one furnace was provided, this method of operation with such high losses of tin in the slag was not commercial, although this slag could be treated again separately. It was found most economical under the prevailing conditions to operate the furnace so as to obtain a metallurgical yield of 96 to 98 per cent. with a higher power consumption.

The following report for the week July 28–August 4, 1910, is fairly typical.

Ore used: 21,056 lb. of 57 per cent. equals	..	12,003 lb. of metal.
Scrap metal and charge refuse equals	.....	2,324 lb. of metal.
Total	.....	14,327 lb. of metal.
Tin produced	.....	14,170 lb.

Net yield, 98·75 per cent.

Total number of kilowatt-hours, 15,113.

From this must be deducted for slag treatment (experimental) 678 kw.-hours, and for preparing furnace, &c., 500 kw.-hours.

Total number of units used for reduction, 13,935.

Units per ton, 2,220.

Electrode consumption, 28 lb. per ton of metal.

It should be noted that this figure for the power consumption was averaged over a single run of eight days, during which experiments with different charges were made. On single days the power consumption was only 1,760 kw.-hours per ton.

One other reason for the larger power consumption was also that the ore was very wet (it contained about 15 per cent. of water), so that the shaft could only be filled to about ⅓ of its height, on account of setting. Also the evaporation of the water wasted a considerable amount of energy.

Conclusions.—The above figures show that a considerable saving in tin can be effected by means of electric smelting. If the plant is so arranged, as is so often done in other metallurgical processes, that two furnaces are working in series, the first one producing metal continuously at a great rate and permitting the hot slag, rich in tin, to run direct into the second furnace for subsequent treatment, eventually with lead ore for solder in order to hasten the process, the power consumption should not exceed 1,400 kw.-hours per ton of tin in a sufficiently large furnace. Even this figure may be decreased if proper blending of ores is strictly attended to. In the above-mentioned cases single ores were mostly used on account of the high price of the ore; this prevented the laying in of a large stock of expensive material for experiments. Also, it should be remembered that in a large commercial plant, modern appliances for tin smelting could be applied, thus again helping to increase the yield and lower the cost.

Another feature is of importance: the electric furnace will commence to yield pure tin even during the first hour of operation, and it will continue to do so without interruption, while the reverberatory furnace is intermittent in its operation. Again, the formation of "hardhead" is materially minimised, whilst the amount of carbon necessary for the reduction is only 14 per cent. instead of 20 to 25 per cent. Less labour is also required, as three ordinary labourers per shift are quite capable of running the furnace. Much less space is necessary for the electric furnace compared with the reverberatory type. The consumption of electrodes is so small that it need not anywhere be regarded as an objectionable feature.

If the power can be obtained at a reasonable rate, it therefore appears to be quite feasible to smelt tin electrically: especially should this be the case in the Straits Settlements, where large quantities of good ore, but not very rich in tin, are mined, and where numerous waterfalls are said to exist, but only a low grade of coal and that in small quantities. The use of charcoal, which probably would be much cheaper, should not be objected to; in fact, with suitable flux, it would probably work even better than culm. Native labour could be employed under white supervision without hesitation, as practically no skilled labour at all is required. It is obvious that it would be much cheaper to ship metallic tin than an ore which, as a rule, only contains about 55 per cent. of tin.

The operations would at first naturally cause a considerable amount of trouble, and would require a good knowledge of metallurgical and chemical engineering, but on the whole one can say that the principles of the problem are solved.

The above experiments will probably be shortly resumed, in a somewhat modified way, by which an even greater saving is to be expected.

STUDIES IN LIGHT PRODUCTION.*

BY R. A. HOUSTOUN, M.A., PH.D., D.SC.
(Lecturer in Physical Optics in the University of Glasgow.)

(*Continued from page 938.*)

Summary.—In these studies the author deals with the theory of light production, the scope being briefly indicated by the following contents: (1) The distribution of the energy in the spectrum and the measuring of efficiency. (2) The importance of "black body" radiation and the experimental realisation of the black body. Comparison of the energy curves of a black body and of platinum, and the variation of the position of maximum energy with temperature. (3) Mechanism of flame, and the temperature, energy and efficiency of flames. (4) The Welsbach mantle and selective radiation. (5) Radiation and efficiency of the carbon glow lamp. (6) Physical properties and temperature of the arc. (7) Temperature and energy curves of the Nernst glower. (8) Efficiency of the metal filament. (9) The mercury arc and its difficulties. (10) The light of the future and the possibility of obtaining "cold light."

No. 4.—The Welsbach Mantle.

The incandescent gas light was invented by Karl Auer, Freiherr von Welsbach, in 1885. He had been a pupil of Bunsen at Heidelberg, and before the invention of the light had made a thorough study of the rare earths. The principle of the light is that a mantle of organic material is impregnated with a mixture of thorium oxide and cerium oxide in the proportion of about one part of the latter to 99 parts of the former; the organic material is then burned off, the oxides remain and are heated in the colourless Bunsen flame until they radiate

* All rights reserved. These contributions, amplified, will be published shortly in "The Electrician" Series.

Digitized by Google

light. It is known that Auer von Welsbach did not come upon the discovery suddenly, but that he experimented systematically with different earths in order to get a mixture which, when heated in the Bunsen flame, would give a stronger light than its components.

On its appearance the Welsbach mantle created quite a stir in the scientific world, and the cause of its brilliancy was very much discussed. It follows quite simply from the ordinary laws of temperature radiation, but at first this was not definitely known, and other explanations such as luminescence and catalysis were forthcoming.

It was assumed that the Welsbach mantle radiated more than a black body at the same temperature, and that, consequently, its radiation could not be pure temperature radiation. Nichols and Snow (Phil. Mag., 33, 1892, p. 19) had found that when platinum foil was covered with zinc oxide and heated electrically to incandescence its light was very strong at first, but that during the first 10 minutes it diminished considerably, although the temperature was kept constant. Afterwards the intensity became constant. Hence they assumed that the light was composed of two parts: one part which remained constant, consisting of temperature radiation, and another part which diminished rapidly, consisting of thermo-luminescence. The source of the energy of this latter part was to be found in a physical or chemical change in the incandescent body, such as one from the amorphous to the crystalline condition. If the Welsbach mantle were thermo-luminescent, we would thus have not only an explanation of its high luminosity but also of the diminution of its intensity with time.

But an experiment described by H. Bunte ("Uber die neure Entwickelung der Flammenbeleuchtung," Ber. d. Deutsch. Chem. Ges., 31, 1898, p. 5) showed that the Welsbach mixture did not radiate more than a black body at the same temperature, and that there was, therefore, no necessity to assume that it was luminescent. A tube of arc lamp carbon which could be heated electrically to over 2,000°C. was used. Magnesia prisms were taken, and faces which met in a sharp edge coated with different substances—carbon, magnesia, thorium oxide, cerium oxide and Welsbach mixture. The prisms were then heated in the tube, and the brightness of the two neighbouring surfaces compared by looking down the end. There was little difference. As the inside of the tube was almost closed, the radiation from its end was practically radiation from a black body, and there should have been little difference, provided that the radiation from the prism was pure temperature radiation. It would, however, have been otherwise had one of the substances been luminescent; hence it follows that the Welsbach mixture is not luminescent.

Killing had maintained that the high luminosity was due to catalysis, and Bunte took up and developed this idea. If platinum black is held over a gas jet, the issuing gas condenses in it and lights up immediately, although the platinum is only at the temperature of the room. A means of lighting the gas is founded on this. The platinum acts as a catalytic agent in facilitating the combination of the oxygen in the air with the coal gas. Bunte supposed that the Welsbach mixture has somewhat the same properties, that it causes the gases to combine more suddenly. A higher temperature is therefore produced, and this explains the increased luminosity. On this theory the diminution of the intensity with time was due to some of the oxide being carried away by the gas and to some of it sintering with dust particles.

Catalysis is, however, not the true explanation, for Le Chatelier and Boudouard (C.R., 126, 1898, p. 1861) showed that when the Welsbach mixture was heated in an atmosphere of the gaseous products of combustion it radiated quite as well as in the Bunsen flame. And Nernst and Bose (Phys. Zs., 1, 1900, p. 289) proved the same result by heating filaments of the mixture electrically and in the Bunsen burner, and showing that the radiation was the same in both cases when the temperature was the same, the latter being measured by the electric resistance of the filament.

The question was finally settled in an article by Rubens; but the true reason for the high luminosity had previously been indicated by Le Chatelier and Boudouard (loc. cit.) and also by Nernst and Bose (loc. cit.). Le Chatelier and Boudouard first showed that the radiation of the Welsbach mixture was less than that of a black body at the same temperature. They then took a thermo-junction, the junction itself being disc shaped and of a diameter of 1·5 mm., and covered it in succession with Welsbach mixture, thorium oxide, cerium oxide, platinum, magnetic iron oxide, uranium oxide and lanthanum oxide, and placed it each time in the same part of the same Bunsen flame. The temperature was then read by the thermo-junction and the brightness compared by means of a spectrophotometer with that of melting platinum for points in the red, green and blue. The results are given in the following table, the brightness of melting platinum being taken as 100 in each case.

——	Tem. perature.	Red.	Green.	Blue.
	Deg. Cent.			
Welsbach mixture	1,380	7·0	12·5	12·5
Thorium oxide.....	1,290	1·45	1·4	0·3
Cerium oxide	1,110	1·9	0·7	0·15
Platinum	1,290	8·5	4·0	1·4
Magnetic iron oxide.....	1,080	1·5	0·48	0·1
Uranium oxide.....	1,070	0·30	0·25	0·05
Lanthanum oxide	1,250	4·0	3·1	1·8

Two striking facts are brought out by this table. First of all the Welsbach mixture attains a temperature 300 deg. higher than a similar black body placed in the same circumstances, for magnetic iron oxide is approximately a black body. Then the relative brightness of the Welsbach mixture increases from red to blue, while it decreases for all the other substances. This high emission in the blue is also brought out by the measurements of Nernst and Bose.

Now the substance in the flame is in a state of thermal equilibrium. It receives, mainly by conduction, a certain fixed quantity of heat per second, and loses it by radiation. The quantity radiated increases with the temperature. Since the temperature of equilibrium of the Welsbach mixture is so much higher than that of magnetic oxide, the Welsbach mixture must radiate very much less when the latter is at the same temperature. In comparison with the other substances, the radiation of the Welsbach mixture falls off as we enter the infra-red. We are, therefore, led to the conclusion that the high luminosity of the Welsbach mantle is due to the fact that it radiates less than the other substances in the infra-red.

In the article above referred to, Rubens ("Uber das Emissionsspektrum des Auerbrenners," Ann. d. Phys. (4), 18, 1905, p. 725) took a complete energy curve (*a*) of a new Welsbach mantle, the glass funnel being removed to avoid absorption in the glass. The mantle was suspended from above in order to eliminate the radiation from the stick in the centre. About 70 points were taken on the curve. The apparatus used was a mirror spectroscope with thermopile; the prisms were of fluorite and sylvin. Then an energy curve (*b*) of the Bunsen alone was taken, and finally the energy curve (*c*) of a mantle that had been dipped in ink and thus covered with a thin layer of iron oxide. When heated in the Bunsen flame the latter mantle reached only a bright red heat. The three curves are given in Fig. 7.

The carbon dioxide bands at 2·8μ and 4·4μ are very prominent. From the curves it is evident that the mantle is practically transparent to the radiation of the Bunsen flame. Hence, by subtracting (*b*) from (*a*), we get the radiation from the mantle alone. This is represented by curve (*d*), in which, for the sake of clearness, the vertical scale is taken twice as large.

Rubens then determined the ratio of the emission of the Welsbach mantle to that of a black body of the same form which was at the same temperature. The result is represented by the curve (*f*), and we see at a glance from this curve why it is that the luminosity of the mantle is so high. Taking the limit of the visible spectrum at 0·7μ, Rubens finds the radiant efficiency of the mantle to be 2 per cent. This 2 per cent. is, of course, extremely effective in producing the sensation of light, owing to there being so much of it in the blue and green.

Digitized by Google

It is necessary that the proportion of thorium and cerium oxide in the mantle should be exactly right; if it is slightly varied the luminosity of the mantle becomes much less. In order to discover the reason for this, and at the same time to investigate the respective roles played by the two oxides, Rubens took an energy curve for (*g*) a mantle in which there was pure thorium oxide alone, and (*h*) a mantle in which there was pure cerium oxide alone. These two curves, together with (*a*), are reproduced in Fig. 8. The only appreciable difference between (*a*) and (*g*) is in the visible spectrum; the shape of (*h*) is, however, quite different, the radiation in the infra-red being much greater than in the case of the other two curves. The addition of a little Ce_2O_3 to the ThO_2 seems, therefore, to move a

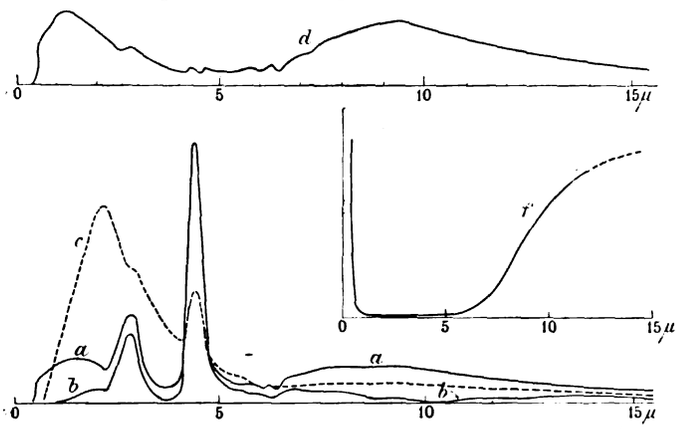

FIG. 7.

maximum into the visible spectrum without affecting the rest of the curve, and to act in somewhat the same way as the sensitising bath in the photography of the red end of the spectrum, while the addition of too much Ce_2O_3 increases the infra-red emission and lowers the temperature.

In a later article ("Emissionsvermögen und Temperatur des Auerstrumpfs bei verschiedenem Cergehalt," Ann. d. Phys. (4) 20, 1906, p. 593) Rubens found that for the mantles he used the best proportion of Ce_2O_3 was about 0·8 per cent.

Le Chatelier and Boudouard (loc. cit.) found by comparing the brightness of some Welsbach mixture on their thermopile with the brightness of a mantle burning normally that the temperature of the latter was 1,650°C. In the first article, referred to above, Rubens stated that the average temperature of the mantle for which the curve (*a*) was given was 1,527°C. As objection was raised to the accuracy of this figure by Lummer

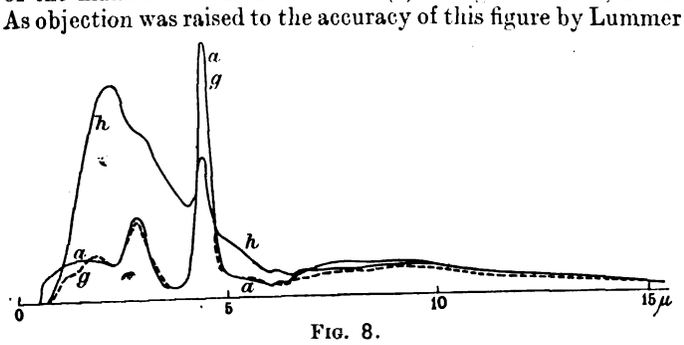

FIG. 8.

and Pringsheim (Phys. Zs., 7, 1906, p. 89; p. 189), he made a further determination (Phys. Zs., 7, 1906, p. 186), placing the mantle at the centre of a hollow sphere, the inside of which was silvered, and measuring the "black" temperature of the radiation from a hole in the side. The maximum values then found for a number of mantles varied from 1,560°C. to 1,590°C. It is interesting to compare this result with a value obtained recently by one of Rubens' students (Hans Schmidt, "Prüfing der Strahlungsgesetze der Bunsenflamme," Ann. d. Phys. (4), 29, 1909, p. 971) for the average temperature of the Bunsen flame itself 2·5 cm. above the edge of the burner. He obtained from about 1,597°C. for the centre to about 1,802°C. for the edge; this is in agreement with the fact that very fine platinum wire can be melted in the Bunsen. One of the previous best determinations had been that of W. J. Waggener (Ann. d. Phys. (3), 58, 1896, p. 579), who used thermopiles of different thickness and then extrapolated for an infinitely thin thermopile. His value was 1,785°C.

It is said that the diminution in intensity of the mantle with time is due to the cerium oxide volatilising more rapidly than the thorium oxide, and that in order to counteract this tendency makers are accustomed to put in rather too much cerium at first.

(*To be continued.*)

REPORT ON MOTOR-GENERATORS, CONVERTERS AND RECTIFIERS.*

BY SILVANUS P. THOMPSON, F.R.S.

1. This Report relates to a class of dynamo-electric machinery the object of which is to change or convert electric energy from one form or variety to another form or variety. From this class of machinery is excluded the apparatus called the transformer, which, though it also converts electric energy from one form to another, does so without employing any revolving parts. Also all those apparatus are excluded which, although they act as rectifiers of alternating currents, effect that operation by chemical means or by means of the electric discharge in vacuous bulbs.

2. *Problem of Conversion.*—The problem of converting electric energy of one form into electric energy of another form presents itself in many aspects, and the solution of it has resulted in many types of machinery. It is possible to consider the subject either by classifying the species of the conversion to be accomplished or by classifying the types of machine. Conversion may be required between any two of the following kinds of current: Continuous current, single-phase alternating current, two-phase alternating current and three-phase alternating current. It may also be required, without altering the kind of current, to convert it with respect to voltage, or frequency, or phase relation, or wave form. Further, the purposes for such conversion may be different, as, for example, for boosting, or balancing, or for gaining variable speed in motor work; and the combinations of machines required for the solutions of these problems are in many cases themselves involved in other problems, such, for example, as the production of a generator of constant voltage working at a variable speed.

As to types of machine, there is a transition of construction from type to type; but the following are the principal types: (*a*) motor-generators with two magnet systems and two armatures; (*b*) motor-generators with one magnet and two armatures; (*c*) motor-generators with one magnet and one armature carrying two windings; (*d*) converters (also called rotary converters) having one magnet system and one armature with one winding; (*e*) cascade converters (also called motor converters) having two interconnected systems (induction motor and continuous-current generator); (*f*) split-pole converters (also called split-pole converters); (*g*) rectifiers; and (*h*) frequency changers. As the machines of this last class are to be dealt with by themselves in a separate Report, they will be but slightly dealt with here. It is more convenient in the present Report to deal with the subject according to types of machine than to classify according to the kind of conversion to be effected. Hence the several types will be considered in systematic order.

3. *Motor-generators with Two Field-magnet Systems and Two Armatures.*—The crudest and most obvious method of conversion is to select a motor appropriate to the primary kind of current, and to couple it mechanically with a generator appropriate to the secondary kind of current. As we shall see, even in the most modern specialised machines to be considered, the apparatus can always be regarded as consisting of two parts, a motor part, with a generator part superposed upon it; and the two functions of the parts may be distinguished even if the parts themselves are so blended as to be mechanically indistinguishable. The mechanical union upon one shaft, or upon two shafts mechanically coupled together, of a motor and a generator is a very old device. Long-distance transmission of electric energy involved from the first high voltage, and also in practice involved the use of alternating currents. Distribution of electric energy in a local network for lighting, power, traction, &c., involved low voltage, and in the majority of cases involved the use of continuous currents. So the particular problem of conversion which presented itself earliest and on the largest scale to engineers was the problem of conversion from high-voltage alternating current (two-phase in earliest times, three-phase in recent years) to low-voltage continuous current. This kind of conversion still remains the dominant kind. An early example of machines so combined is furnished by the motor-generators installed in 1890 in the town of Cassel by Oscar von Miller, consisting of a synchronous monophase alterna-

* Report presented at the recent International Congress of Applications of Electricity, held at Turin.

Digitized by Google

of 66 k.v.a., working at 2,000 volts, coupled mechanically at each end of its shaft to a bipolar continuous-current generator giving each 210 amperes at 110 volts, the two generators feeding the two sides of a three-wire network. Modern motor-generator sets almost always consist of high-voltage three-phase synchronous motors coupled to low-voltage continuous-current generators. All the chief constructive firms of Europe supply such motor-generators for traction and lighting, and they are in extensive use. A typical example is afforded by the motor-generators (six) supplied recently by Messrs. Dick, Kerr & Co., (Ltd.), of Preston, to the Calcutta Electric Supply Corpn., consisting of a synchronous three-phase 14-pole motor, rated at 500 k.v.a., running at 428 revs. per min., giving 6,000 volts at 50 cycles per second, coupled direct to a continuous-current generator with six poles, of 450 kw. output, shunt wound, working at 450 to 550 volts, and having commutating poles. Such machines have no electrical connection whatever between their two parts. The whole of the electrical energy supplied (save the inevitable losses) is converted into mechanical energy delivered to the revolving shaft, and is at once reconverted into electrical energy in the generator part. Such machines are not self-starting, but must be brought up to synchronism either by being temporarily supplied on their continuous-current side, or else by means of an auxiliary induction-motor used as starter. As there are in them two sets of electrical and magnetic losses, as well as mechanical losses, the efficiency is limited. But they have the advantage that the regulation of the power factor on the primary side and of the voltage on the secondary side can be independently effected by varying the respective excitations of the two field-magnet systems.

Such motor-generators can also be used for the converse problem of converting from continuous current to alternating current.

Motor-generator combinations can obviously be arranged in other ways. Instead of a synchronous motor, an asynchronous motor can be used, and in this case the machine is self-starting. Also the combination of two different alternating machines as motor and generator might be used to convert from single phase to two phase or three phase, or to change the frequency, or as a phase-shifter, or to alter the wave form or the voltage. Commutator motors for single-phase current do not appear to have yet been employed in motor-generators. They might even be used for the generator part as well as for the motor part. The combination of an asynchronous motor with a synchronous generator possesses special properties making it useful as a frequency changer.

4. *Motor-Generators with one Magnet and two Armatures.*—Such machines are the first stage toward the synthesis of the two parts. The same field magnet, made broad enough to embrace both armatures, is a possible type of construction, but it limits the applications of the machine in various ways. With this construction no synchronous alternating-current motor or generator is possible. Voltage regulation takes a different aspect, because any change in the excitation of the magnet affects both parts. Nevertheless, on this plan there have been at times constructed continuous-current converters.

5. *Motor-Generators with one Magnet and one Armature with two Independent Windings.*—The next stage toward fusion of the two parts is to provide a single armature core, but to wind it with two independent windings. If each winding is provided with its own commutator the machine becomes a continuous-current converter, suitable for receiving a current at one voltage and giving it out at another according to the ratio of the number of armature windings. Such a machine was indeed constructed by Gramme as early as 1874. If used as continuous-current balancer it is defective, since, as the magnetic field is common to both windings, there is no independent regulation of the voltage by changing the excitation.

By making one winding extend a longer distance than the other (axially) along the armature core, and applying to this extended part of the core an auxiliary field magnet, an independent regulation of the voltage may be obtained; and if this auxiliary magnet is excited by the (continuous) current entering or leaving the machine it will automatically vary the voltage as the load rises or falls. A continuous-current converter of this type may be arranged as a balancer by having two identical windings and two commutators, the E.M.F. of which are then put in series, the negative brush from one side and the positive brush from the other being joined to the neutral wire of a three-wire distribution. A further possible arrangement is to have at the motor side a high-voltage winding, with its appropriate commutator and at the generator side two independent low-voltage windings, each with its own commutator, these two secondary windings generating equal E.M.F. to supply the two sides of a three-wire distribution. One can imagine also a balancer for a five-wire distribution by providing the armature with four independent (equal) windings each with its own commutator, the four windings being put in series by connections at the brushes. If in a machine of this type any alternating-current winding designed in accordance with the number of poles, and connected down to the appropriate number of slip-rings for monophase, diphase, or triphase working, be wound on the armature, that side of the armature will serve for either synchronous motor or synchronous generator. If both windings are of this description this type may be used as phase changer, but not as frequency changer. With one such alternate-current winding, combined with a continuous-current winding the machine acts as a synchronous converter.

6. *Converters* (also called *Rotary Converters*). In this type there is but one field-magnet system, excited in shunt (from the continuous-current side), or independently, or compound-wound, and but one armature winding. This winding is connected at one side to an ordinary commutator, but is also connected, at the other side, at points symmetrically chosen, with respect to the windings and to the number of pole-pairs, to an appropriate number of slip-rings. The advantages and limitations of this type are very well known. The machine runs only as a synchronous machine. It is not self-starting from the alternating-current side. Except by special provision mentioned hereafter it does not permit of independent regulation of the voltage, the voltage between the brushes on the continuous-current side being practically in a fixed ratio to that between the slip-rings on the alternating side. Though such a machine can be used to convert from alternating current (of one, two, or more phases) to continuous current, or vice versa, it cannot of itself fulfil the condition of solving the dominant problem of changing from high voltage to low; therefore in all such cases step-down transformers are needed to reduce the voltage. Owing to there being but one armature winding, the sources of loss of energy are reduced, particularly if the number of phases by which the currents are introduced on the alternating side is great. Converters with six slip-rings wound for six-phase current are more efficient than those with but three; and it is easy to arrange the windings on the three-phase step-down transformer so that it yields six-phase current on its secondary side. The efficiency of transformers is so high that the total losses for transformer and rotary converter are less than those of a motor-generator set of equal output.

A long controversy has raged between the advocates of converters and those of motor-generators. All sorts of disadvantages have been attributed to converters; not only was their voltage fixed so that regulation was difficult, but when running in parallel they were apt to "hunt"; they were apt to reverse polarity; they were— at least unless designed for very low frequency, and with consequent wide pole-pitch—apt to flash over at the commutator. All these defects have been successfully combatted. Converters working at frequencies of 50 or even 60 cycles per second can be designed to give satisfaction, though undoubtedly frequencies of 33 or 25 are preferable. The addition of an amortisseur in the poles has eliminated "hunting." The problem of regulating the voltage has found several solutions. By using transformers having considerable self-induction in their secondary circuits, or by introducing into their secondary circuits between the transformer and the converter appropriate self-induction coils, it has been possible to regulate the voltage on the continuous-current side by merely varying the excitation of the field-magnet; increasing the excitation raises the voltage on the continuous side, and while it necessarily also raises the alternating voltage of reaction, it tends to put forward the phase angle and counteract the drop in the power factor due to the self-induction of the transformer. A second method of regulation is to add a synchronous booster on the shaft of the converter, the voltage of the incoming alternating currents being increased as the continuous-current output increases. A third method is to design the polar parts of the field-magnet so as to alter the wave-form of the alternating E.M.F. induced by the armature. The devices of Woodbridge for surrounding portions of each pole by coils for increasing or diminishing the magnetic flux in the pole-tips as compared with the flux in the central part of the pole afford a tolerable though not an automatic means of regulation. In a modification due to Burnham each pole is divided into two parts, the excitations of which can be independently controlled. A fourth method due to Miles Walker is to design the field-magnet of the converter to give a carefully graduated commutation zone, so that the voltage may be regulated by varying the lead given to the brushes.

Modern opinion seems to favour the use of converters in lieu of motor-generator sets, and the objections to them appear to have been largely overcome. They are occasionally designed with vertical shafts to economise space. Two rotary converters united together at their continuous-current sides might work as a frequency-changer, due regard being had to the number of poles and voltages.

7. *Cascade Converters.*—In these machines the two parts consist of an induction motor and a continuous-current generator interconnected electrically as well as mechanically. The motor part is an induction motor, into the stator of which the high-voltage three-phase current is brought. The rotor is on the same shaft as the armature of a continuous-current generator, and is connected to that armature electrically, the armature windings being connected back

Digitized by Google

symmetrically to the windings of the rotor precisely as the armature windings are connected back to the slip-rings in a rotary converter. As a result the rotor runs synchronously, with a constant slip of 50 per cent., and half the power is transmitted electrically direct through the armature to the brushes, while the other half of the power drives the armature mechanically and generates the remaining half of the output delivered to the brushes. The efficiency of the machine is high, in general rivalling that of the combined rotary converter and transformer, and surpassing that of the simple motor-generator set of equal output. So much has been written upon the cascade converter by Arnold, Bragstad, La Cour and Hallo that no extended notice is here necessary. Cascade converters are now usually built as 12-phase machines in the rotor part, and with commutating poles on the field magnet. They also can be built with an alternating booster between rotor and armature for procuring independent voltage regulation.

8. *Revolving Field Converters.*—A curious type of machine is one in which the motor part resembles an ordinary alternator, the stator of which being, however, provided with two windings. One of these, an ordinary stator winding, receives the incoming high-voltage currents. The other winding, in the same slots, is an ordinary drum winding for the same number of poles, connected down to a commutator, which is stationary. The brushes revolve synchronously (pressing against the inside surface of the commutator), being carried round by the revolving field magnet, which runs synchronously. The poles of the field magnet need not be wound, being magnetised by the stator currents. In this case the electric energy is transformed and converted electrically. As thus described the machine is Arnold's modification of an earlier and more complex apparatus of Hutin and Leblanc, in which not even the iron of the field magnet revolved. The "Permutatrice" of Rougé and Fayet is esentially the same contrivance, but in it the brushes revolve externally to a fixed commutator of ordinary construction. The "Permutator" of Sahulka is of the same type.

9. *Rectifiers.*—From such machines as the foregoing, in which synchronously revolving brushes receive the continuous current, it is but a step to the much older rectifiers, by which it was sought to procure a uni-directional current from a simple alternating one by merely passing it through a synchronously revolving commutator or reverser. The rectifying commutator used in Wilde's alternators and later in those of Zipernowsky was an early example. Still later came the rectifiers of Pollak for accumulator charging, and of Ferranti for arc lighting. But none of these were satisfactory for rectifying large currents, since in the first place there was difficulty about sparking, and in the second the currents so rectified were pulsatory in character and not really continuous. Heyland's commutator for making a three-phase generator self-exciting belongs to the class of rectifiers, as the brushes on the commutator reverse the alternating currents synchronously without being provided with a magnetic field to procure sparkless commutation.

10. *Frequency Changers.*—Various combinations are possible. Two synchronous alternators with appropriate numbers of poles, coupled on one shaft, would form a motor-generator set suitable for this purpose. Steinmetz has suggested the combination of a synchronous and an asynchronous machine, but the latter cannot be used as the generator unless the system it supplies has other synchronous machines upon it to fix the frequency. The case of a pair of coupled rotary converters has already been mentioned; and a pair of cascade converters might also serve the same object. A more hopeful suggestion is to couple mechanically the rotors of a pair of ordinary induction motors of appropriate voltages and numbers of poles, the combined machine running at such a speed as to be below synchronism for the motor machine and above synchronism for the generator machine. Such a combination would serve for interconnection of the networks of two generating stations.

11. *Phase Shifters.*—For the infrequent purpose of changing or shifting the phase of an alternating current, machines are occasionally needed, and the principle of them is simple. Consider an ordinary induction motor. The currents coming into the stator there conspire to produce a progressive or rotatory magnetic field. If a coil be wound on the stator through two slots which are a pole-pitch apart there will be induced in that coil an alternating E.M.F. of the same period; but the phase of this E.M.F. will depend on the position of the slots with respect to the rest of the windings. If two such coils are wound in different positions the phase difference between their respective E.M.F.s will depend solely on the angle by which their positions differ. Hence one could easily wind a stator with two sets of windings, a primary or motor winding and a secondary or generator winding, the latter giving out alternating currents of the same frequency, but of different phase angle, or even with a different number of phases from that of the primary current. Thus a machine may be constructed to convert three-phase current into two phase or single phase, or to convert single phase into two phase or three phase. Such phase transformers were suggested independently by the author and by Arno. Another method is to couple together the revolving field magnets of a pair of ordinary synchronous alternators, one to serve as motor the other as generator. By shifting the stator of either machine through the appropriate angle any desired phase difference between their respective E.M.F.s can be obtained. Such a combination has been used to shift the load of a network from one generating station to another.

12. *Auto-Converters.*—The next recent type of converting machine is the auto-converter (also called the split-pole converter), the chief characteristic of which is the construction of the field-magnet with twice as many polar projections as there are poles in the winding of the armature, these magnet poles being arranged in pairs of the same polarity. As these machines seem destined to have an important future, some extended notice of them is desirable.

Consider Fig. 1 a two-pole armature with its ordinary windings and commutator. The windings span approximately across a diameter, and the two brushes stand at opposite ends of a diameter. There are two-pole pitches or regions, one usually occupied by the north pole, the other by the south pole of the magnet system. If the brushes are placed in the usual positions for collecting current ("neutral points,") the difference of potential between them (on open circuit) is then a maximum. If shifted through half a pole-pitch, that is, through a right angle, the difference of potential between them is reduced to zero. By adopting the modern method of compensating windings, current can be collected sparklessly, without giving the brushes any lead.

Suppose now we divide each of the poles of the field-magnet into two, so that the north pole N is replaced by the two poles N_1 and N_2, and that the south pole S is replaced by the two poles S_1 and S_2, as in Fig. 2. The pair N_1, S_1 may be considered as belonging to one magnetic circuit, the pair N_2, S_2 as belonging to a second and independent magnetic circuit at right angles to the first. If the first pair only is excited, the voltage between the brushes A_1, A_2 will be that due to N_1, S_1; if the second pair only is excited the voltage between the brushes A_1, A_2 will be that due to N_2, S_2. If both pairs are excited, the voltage between the brushes A_1, A_2 will be that due to the whole flux from N_1 and N_2, through the armature, to S_1 and S_2. Now suppose a second set of brushes B_1, B_2 placed in a position at right angles to A_1, A_2. It is obvious that if both pairs of poles are excited the voltage between these two will be that due to the difference between the two fluxes of the magnetic circuits. If we call the two fluxes F_1 and F_2 respectively, the voltage across A_1, A_2 will be proportional to F_1+F_2 and that across B_1, B_2 to F_1-F_2. (If we consider the partial voltages across from A_1 to B_1 and from B_1 to A_2, these will respectively be proportional to F_1 and F_2.) If now exciting coils are wound on these poles such that F_1 is made proportional to the sum of the A and B voltages, and that F_2 is made proportional to the difference of the A and B voltages, as can be effected by shunt coils which are wound summationally on the pair N_1, S_1 and differentially on the pair N_2, S_2, then the generated A voltage which is proportional to F_1+F_2 will depend on the A excitation only, and the generated B voltage which is proportional to F_1-F_2 will depend on the B excitation only; in other words each half of the machine will act as an independent self-excited shunt-wound machine. Each may, of course, be also compound wound, or might even be merely series-wound following an analogous plan. Fig. 3 depicts the combination arranged as a four-pole machine; but in reality it consists of a single armature acted upon by two independent two-pole field-magnets. The single machine so arranged becomes therefore the equivalent of two independent machines coupled together. So far, we have described it as a double generator, but obviously it can be used as a continuous-current converter. The term "auto-converter" is more descriptive seeing that there is only one armature winding. If a continuous current is applied to the brushes A_1, A_2 it will run as a motor, and an independent continuous-current will be generated in it, and delivered at the brushes B_1, B_2. If the pole-sections and windings are alike, the fluxes will be equal and the voltages equal. They can be made unequal by altering the pole sections or reluctances of the magnetic circuits, or the resistances of the exciting circuits, or by shifting the brushes to intermediate angles. With appropriate

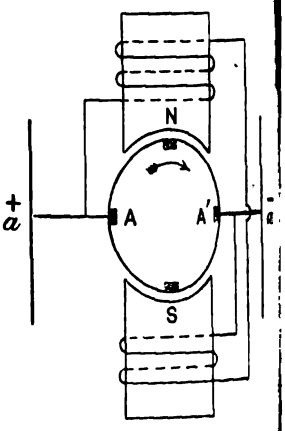

FIG. 1.

Digitized by Google

modifications such a machine can be used as balancer, or booster, or as a three-wire generator.

If instead of adopting the method of excitation described above, one of the magnet pairs N_1, S_1 is independently excited and the second magnet pair N_2, S_2 is excited from the brushes pertaining to the field of the first pair, the machine then becomes a variable-speed generator and will furnish an approximately constant voltage at any speed, in either direction of rotation, as required for train lighting.

Now suppose the same armature to be connected at the appropriate symmetrical points to three slip-rings. The same machine will then be capable of being used as an alternating-continuous con-

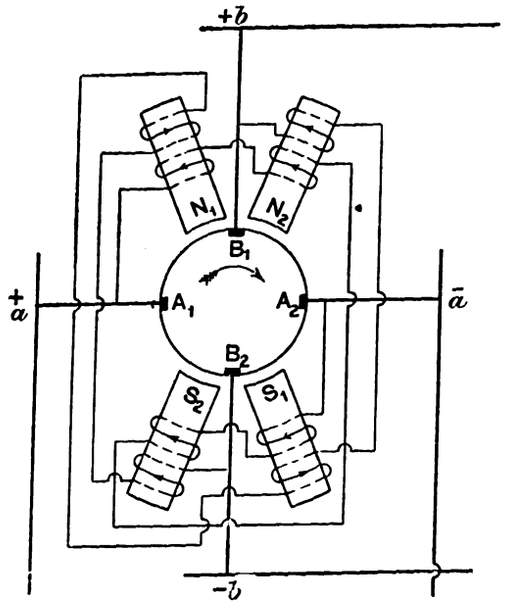

Fig. 2.

verter, and could furnish two different continuous currents at the same time, at equal or different voltages. It must, of course, run synchronously.

In the foregoing it has been assumed that armature reaction is absent or has been compensated. If instead of compensating armature reaction it is enhanced by short-circuiting one pair of brushes, fresh developments are possible; and on this procedure have been based a number of interesting machines such as: the train-lighting generators of Roenberg, Midgeley and others, and Woodbridge's exciter for three-phase systems. Of auto-converters that

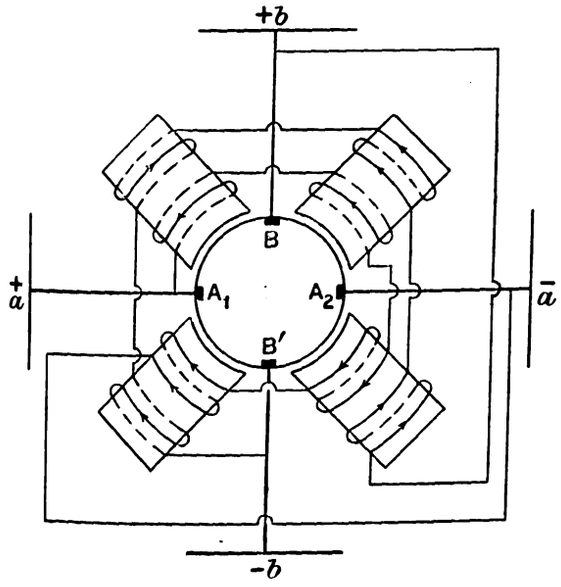

Fig. 3.

of Crompton-Macfarlane-Burge has obtained wide application. Considered in its bipolar form the generator E.M.F. is tapped off at the commutator between one of the A_1, A_2 brushes of the motor circuit and a pair of connected B brushes situated at equipotential points, not necessarily on a diameter at right angles to A_1, A_2. To make these B points equi-distant from the A brush as well as equi-potential, the two divided pole pairs are arranged in bilateral symmetry with respect to the A_1, A_2 axis, N_1 being the same size as S_2 and N_2 as S_1.

These machines are being used (1) as step-down continuous-current converters; (2) as voltage regulators; (3) as converters to convert from variable current at constant voltage to constant current within a limited range; (4) as rotary converters affording regulation of the continuous voltage without affecting the power-factor on the alternating side.

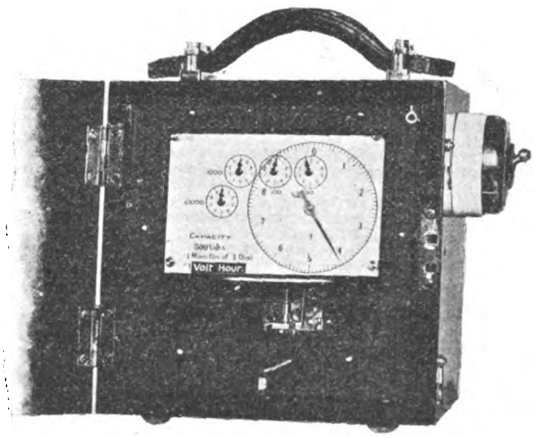
VOLT-HOUR METERS.

A new volt-hour meter, which, it is believed, will commend itself for use in various directions, but particularly in connection with tramway undertakings, has recently been suggested by Messrs. R. G. Cunliffe and J. G. Cunliffe (of the Manchester Corporation Tramways) and has been developed by the British Westinghouse Electric & Manufacturing Co.

This meter, of which a view is given herewith, is referred to in a Paper on "Tramcar Meters" read yesterday by Messrs. Cunliffe at the Annual Conference of the Municipal Tramways Association which is being held this week at Glasgow.

The new meter is, in principle, a direct-current motor in its simplest form, having a moving armature of a special and simple design; and it is designed so that the speed of the armature is proportional to the voltage. The meter is arranged to read in volt-hours; thus, at the end of one hour the average voltage of the circuit during that hour is indicated directly on the dial. As subsequent checking and recalibration is a simple matter, requiring little skill and no special apparatus, the high degree of accuracy with which the meter is originally calibrated can be easily maintained.

The importance to tramway managers and engineers of keeping a constant check on the average voltage of various sections of their



Volt-hour Meter of the British Westinghouse Co.

systems, both during normal working and under special service conditions, will undoubtedly be fully realised. Where the voltage becomes too low, owing to long feeders, long trolley lines, or heavy loading, serious losses are incurred; these include loss of energy in transmission, loss in the car equipment through inefficient working consequent on low voltage, and undue heating of feeders and trolley wires. Not only so, but low voltage means reduced speed, and that to keep to schedule time a driver may be compelled to use energy in driving where otherwise with higher voltage he would be able to coast.

Another direction where a knowledge of the average voltage on a circuit is desirable is in connection with tramway systems using ampere-hour meters on the cars. Conclusions based on readings taken in amperes only may be seriously misleading, and therefore the average voltage during the period of registration should be known, the readings in ampere-hours being corrected to represent the actual energy expended.

Up to the present time, instruments recording with a pen upon a paper chart have been used to determine average voltages. There is, however, with this arrangement a likelihood of errors resulting from the friction between the pen and the paper: moreover, when meters of this type are used on tramcars, a further and more serious error is introduced by the frequent stopping and starting causing vibration and jolting of the pen. The new meter has neither pen nor paper, and is therefore free from the drawbacks indicated. It can be used either in a stationary position or upon a car and has the advantage of recording directly upon a dial. Moreover, being exceedingly simple in construction it can be had at a comparatively low cost.

The Rates for Subscription to "THE ELECTRICIAN" are as under:—

	Year.	Half-Year.	Quarter.	
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.	Post free, payable in advance.
Canada	28s. 3d.	14s. 6d.	7s. 6d.	
Postal Union ...	30s. 0d.	16s. 0d.	8s. 0d.	

New volumes of "THE ELECTRICIAN" *commence in April and October.*

(This charge includes all the numerous Supplements.)

Vols. I to LXVI. can now be supplied. Price on application.

"THE ELECTRICIAN" SERIES OF STANDARD ELECTRICAL BOOKS

can be obtained of all Booksellers at Home, in the Colonies, and Abroad.

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. Published annually in February, corrected to mid-February. Established 1882. A very valuable advertising medium, covering the entire Industry. SUBSCRIPTION Price (which is received *in advance* up to Jan. 31st in each year for the next following edition) 8s 6d. nett, postage 9d. extra. Published price 15s. nett, postage 9d. extra. Postage to British Colonies, 2s; Europe, 2s; U.S.A., 3s. 6d.; other countries, 2s. 6d. *Digest of Contents of the 1911 Edition sent free on application.*

THE PRACTICAL WIRELESS SLIDE RULE. By Dr. H. R. Belcher-Hickman. Price 2s. 6d. nett. *Reduction on quantity.*

LIVINGSTONE'S DIAGRAM FOR THE EASY CALCULATION OF SHAFT AND BEAM DEFLECTIONS. By R. Livingstone. 2s. 6d. nett. By post in tube, 2s. 10d.

"THE ELECTRICIAN" PRIMERS (81 Primers in all, and a GLOSSARY). Single Primers 3d. each post free. *New and Enlarged Edition in One Complete Vol. or Three Separate Vols.* FULL PROSPECTUS FREE.

ELECTRIC TRACTION ON RAILWAYS. By Philip Dawson. Price 25s. nett. *Prospectus free.*

ALTERNATING-CURRENT MOTORS. By Dr. Rudolf Goldschmidt. Price 6s. 6d.

THE SHOT-FIRER'S GUIDE: A Practical Manual on Blasting and the Prevention of Blasting Accidents in Mines, Quarries, &c. By W. Maurice. Price 3s. 6d. nett.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. Wilkinson, M.I.E.E. *New Edition.* Now ready. Price 15s. nett.

ELECTRIC BLASTING APPARATUS AND EXPLOSIVES: With Special Reference to Colliery Practice. By W. Maurice. Price 8s. 6d. nett.

THE ELECTRIC FURNACE IN IRON AND STEEL PRODUCTION. By John B. C. Kershaw, F.I.C. Price 3s. 6d. nett.

BRAKES FOR TRAMWAY CARS. By H. M. Sayers. Price 3s. 6d. nett.

THE MECHANICAL DESIGN AND CONSTRUCTION OF COMMUTATORS. By R. Livingstone. Price 6s. nett.

THE ALTERNATE-CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. [abroad 13s.

VOL. I.—Price 12s. 6d. post free, abroad 13s. VOL. II.—Price 12s. 6d. post free, abroad 13s.

HANDBOOK OF THE ELECTRICAL LABORATORY AND TESTING ROOM. Very fully illustrated. By Dr. J. A. Fleming. Vol. I., 12s. 6d. nett, Vol. II., 14s. nett.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. Fleming. 6s. nett.

ELECTRICAL LABORATORY NOTES AND FORMS. Arranged by Dr. J. A. Fleming, M.A., F.R.S. Single copies 4d. nett, or in dozens at 3s. 6d. nett. Complete Sets of 50 Notes and Forms, 12s. 6d. nett, or in strong portfolio, 14s. nett; or bound in strong cloth, 15s. nett. Spare Copies of Tabular Sheets, 1s. per dozen. Portfolios, 1s. 6d. each. Sectional paper, 1s. per dozen sheets. *Complete Prospectus post free on request.*

ELECTRICITY METERS: THEIR CONSTRUCTION AND MANAGEMENT. By C. H. W. Gerhardi. Profusely illustrated. Price 9s. nett.

ELECTRICITY IN HORTICULTURE. By Prof. S. Lemstrom. Illustrated. 3s. 6d nett.

RADIO-ACTIVITY: AN ELEMENTARY TREATISE FROM THE STANDPOINT OF THE DISINTEGRATION THEORY. By Fredk. Soddy, M.A. Fully illustrated. Price 6s. 6d. nett.

ELECTROMAGNETIC THEORY. By Oliver Heaviside. Vol. I. Price 12s. 6d. Vol. II. Price 12s. 6d. *Vol. III. in the press.*

MOTIVE POWER AND GEARING FOR ELECTRICAL MACHINERY. By E. Tremlett Carter, C.E., M.I.E.E. Revised by G. Thomas-Davies, A.M.I.E.E., F.C.S. Price 12s. 6d. nett.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. Ewing, B.Sc., F.R.S., F.R.S.E. Price 10s. 6d.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. Kennelly and H. D. Wilkinson, M.I.E.E. Price 6s. 6d.

ELECTRIC MOTIVE POWER. By Albion T. Snell. Price 10s. 6d. nett.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. Geipel and H. M. Kilgour. Price 7s. 6d. nett.

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. Elton Young. Price 10s. 6d.

STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By H. K. C. Fisher and J. C. H. Darby. Price 7s. 6d. nett.

SIGNALLING ACROSS SPACE WITHOUT WIRES: THE WORK OF HERTZ AND HIS SUCCESSORS. With new Chapter on Tuning. By Dr. Sir Oliver J. Lodge. Price 5s. nett.

THE ART OF ELECTROLYTIC SEPARATION OF METALS. By Dr. G. Gore, LL.D., F.R.S.

ELECTRO-CHEMISTRY. By Dr. George Gore. Price 2s. [Price 10s. 6d.

BEGINNER'S MANUAL OF SUBMARINE CABLE TESTING AND WORKING. By G. M. Baines. Price 7s. 6d. nett.

CARBON MAKING FOR ALL ELECTRICAL PURPOSES. By Francis Jehl. Price 10s. 6d.

"THE ELECTRICIAN" WIREMAN'S POCKET BOOK. Price 5s. nett.

"THE ELECTRICIAN" HANDY WIRE TABLES FOR THE POCKET. By P. B. Down, Wh.Ex., A.M.I.Mech.E. Price 2s. 6d. nett.

THE RATING OF ELECTRIC LIGHTING, ELECTRIC TRAMWAY, AND SIMILAR UNDERTAKINGS. By W. C. Bond, M.I.E.E. Price 2s. 6d. nett.

DRUM ARMATURE WINDING AND COMMUTATORS. By F. M. Weymouth. 7s. 6d.

PRIMARY BATTERIES: THEIR CONSTRUCTION AND MANUFACTURE. By W. R. Cooper. Price 10s. 6d. nett.

SECONDARY BATTERIES: THEIR CONSTRUCTION AND MANUFACTURE. By E. J. Wade. [Price 10s. 6d. nett.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. Price 1s. 6d.

THE LOCALISATION OF FAULTS IN ELECTRIC LIGHT CABLES. By F. C. Raphael. 7s. 6d.

THE STEAM-ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. Beaumont, M.I.C.E., M.I.M.E., &c. Price 6s. nett.

THE ELECTRIC ARC. By Mrs. Ayrton. M.I.E.E. Price 12s. 6d.

TRAMWAY TRACTIVE EFFORT AND POWER DIAGRAM. By Arnold G. Hansard, B.A., A.M.I.E.E. Price 4s. 6d. nett; in Tube, 5s.

THE BRITISH POST OFFICE TELEPHONE SERVICE. Fully illustrated. Price 3s. 6d. nett.

INTERNATIONAL TELEGRAPH CONVENTION AND SERVICE REGULATIONS. Price 6s. nett. (LISBON REVISION, 1908.)

BOILER FEED WATER. By F. W. Anderson. Price 6s. nett.

(PRELIMINARY) WIRELESS TELEGRAPH CONFERENCE (BERLIN, 1903), PROCEEDINGS AT. Price 8s. 6d. nett.

INTERNATIONAL WIRELESS TELEGRAPH CONVENTION AND SERVICE REGULATIONS (BERLIN, 1906). With complete report of Proceedings. Price 21s. nett.

THE TWO-TONE VIBRATING TRANSMITTER AND CABLE INDUCTIVE SIGNALLING. By Edward Raymond-Barker. Price 1s. nett and post free. [Price 3s. nett.

THE CLASSIFICATION OF ALTERNATE-CURRENT MOTORS. By V. A. A. Fynn, M.I.E.E.

ELECTRIC CRANES: THEIR DESIGN, CONSTRUCTION AND APPLICATION. By H. H. Broughton. Being Vol. I. of a Complete Manual of Lifting and Hauling Machinery. *Now Ready*, price 25s. nett.

AITKEN'S MANUAL OF THE TELEPHONE. By W. Aitken, M.I.E.E. *Ready in October.*

ELECTRIC MAINS AND DISTRIBUTING SYSTEMS. By J. R. Dick, B.Sc., and F. Fernie, A.M.Inst.C.E. *Ready in October.*

WIREMAN'S POCKET BOOK AND ELECTRICAL CONTRACTOR'S HANDBOOK. Compiled by A. W. Robinson and W. E. Warrilow. Price 5s. nett. *Ready in October.*

AMATEUR WIRELESS TELEGRAPH DESIGNS. By "Alfred." Very fully illustrated. *Now Ready.* Price 1s. 6d. nett.

ELECTRICAL MANUAL FOR MINING ENGINEERS. By H. J. S. Heather, M.I.E.E. *Ready in December.* *[In Preparation.*

THE MECHANICAL DESIGN AND CONSTRUCTION OF GENERATORS. By R. Livingstone.

STUDIES IN LIGHT PRODUCTION. By R. A. Houston, M.A., Ph.D., D.Sc. *In Preparation.*

LIGHT: RADIATION AND ILLUMINATION. From the German of Paul Hogner, by Justus Eck. *In Preparation.*

The Electrician.

The Oldest Electrical Journal (established as a weekly Journal, 1861-1878)

Published every Friday, Price Sixpence; Post Free, Sixpence-Halfpenny.

Editorial, Publishing and Printing Offices,

"THE ELECTRICIAN" INDUSTRIAL SUPPLEMENT.

With "THE ELECTRICIAN" for Sept. 14, 1906, was issued the first of a series of "Industrial Supplements," to be published from time to time with "THE ELECTRICIAN." The fifty-third issue of the Supplement published (Gratis) with the number of "THE ELECTRICIAN" for September 23, 1910, was the last of the monthly issues. "THE COMMERCIAL AND INDUSTRIAL SUPPLEMENT" to "THE ELECTRICIAN" is now issued weekly (Gratis). It will be found towards the end of the present issue.

NEARLY READY.

Vol. LXVII. of "THE ELECTRICIAN." Bound in Publisher's covers. Price 17s. 6d. Postage U.K. 1s. extra, abroad 2s. 6d.

Cases for binding Vol. LXVI. now ready, price 2s.; post free, 2s. 3d.

ELECTRICITY SUPPLY FOR RAILWAYS.

One of the objections sometimes put forward to the introduction of electrical working on a railway is the outlay necessary for the erection of a station for generating the required electrical energy. Yet advantage is seldom taken of an outside supply. In a Paper read a short time ago before the National Electric Light Association, Mr. F. DARLINGTON pointed out that in America only one electrically-operated trunk railway is supplied with energy from a public power station, it being the custom for the railways to instal independent generating plant. In glancing from time to time through the pages of our American contemporaries one cannot, indeed, help noticing the large number of comparatively small stations that have been constructed for supplying the numerous electric railways in that country. In many cases, no doubt, an alternative supply of power was not available, but with the exception of the Commonwealth Company, of Chicago, and a few other large concerns, little effort has apparently been made to deal with traction loads from existing power stations.

It is becoming increasingly recognised at the present time that generating electrical energy is a business in itself, and that it is best to leave this work in the hands of those who make it their primary object. Thus it is that numerous private plants have been superseded by a supply from public mains. With small private plants the saving that is possible by adopting this course is fairly obvious, and even in large concerns, such as mines, a saving is often effected. Only in a recent issue of THE ELECTRICIAN attention was

Digitized by Google

drawn to the fact that by changing over from steam power to electric power obtained from the Victoria Falls & Transvaal Power Co. a saving was effected by one of the mines equal to 7·28d. per ton milled.

The position of a railway is somewhat special in regard to this question, because a large engineering staff must in any case be employed; also the district served is often large, and money is obtainable on easy terms. Nevertheless, the engineering problems on a railway are not the same as those occurring in the generation of electrical energy, and it is probably better that the energies of the staff should be restricted to the varied engineering problems of the railway proper rather than spread over a larger sphere obtained by including problems of electric generation. Of course, it may be that a suitable public supply is not available, for the power required by a railway is large; or, possibly, the distance for transmission is considerable, so that the conditions are unfavourable as compared with a generating station on the line itself. This state of things, however, with the growth of electric power, should become less and less prevalent.

In the event of extensive railway electrification in this country, the question of supplying the necessary power would probably give rise to considerable discussion. At present the Midland Railway Co. and the Lancashire & Yorkshire Railway Co. possess their own power stations for supplying current to the electrified sections of their tracks, whilst the North-Eastern Railway Co. and the London, Brighton & South Coast Railway Co. prefer to purchase power. Again, some of the underground railways of London have individual generating stations, although most of them are grouped together and obtain their power from a single station at Lot's-road, which is operated as a separate branch. It may be remembered that in connection with the recent Bill of the Metropolitan District and London Electric Railway Companies for sanction to purchase the Lot's-road power station of the Underground Electric Railways Co. of London, the future position of this station as regards the supply of power to other undertakings was raised a few months ago. It was decided to allow a supply of electrical energy to be given when required to the Central London, the City & South London, the Great Northern & City, the London & North-Western and the North London Railways respectively, the present capacity of the plant at Lot's-road—namely, 48,000 kw.—being capable of extension to 180,000 kw.

The advantages of combining the supply of energy for traction purposes near London in one station are, of course, many, particularly as regards load-factor and diversity-factor; but from the point of view of reliability such a course is scarcely desirable, since in the event of a breakdown, such as occurred a year or two ago at Lot's-road, the dislocation of traffic would be widespread and disastrous. From this point of view, as well as from that of undesirable competition with existing supply authorities, many of whom should be able to meet the demand of the railways, undue concentration of supply might prove not altogether advantageous. On the other hand, it would be undesirable for a number of independent generating stations to be erected about the country for this purpose. The present power supply companies should be particularly well adapted to deal with the requirements of the railways, and decided encouragement would be given to the business of electricity supply in bulk.

REVIEWS.

(Copies of the undermentioned works can be had from THE ELECTRICIAN Office, post free, on receipt of published price, adding 3d. for books published under 2s. Add 10 per cent. for abroad or for foreign books.)

Electric Crane Construction. By C. W. HILL. (London, 1911: C. Griffin & Co.) Pp. xx. + 313. 25s. nett.

Probably in no branch of engineering are there fewer works of reference than in that which deals with the construction of lifting and hauling machinery. Not that the literature is scanty, but to the rank and file and to the busy engineer it is not an easy matter to search for the information. An enquiry comes into the office and no time must be lost in preparing preliminary drawings and estimates. Like Kipling's Midshipman, the designer "must do what he is told—not immediately but sooner, much sooner." Those familiar with the crane industry know that at the present time, on account of the keen competition, makers must be prepared to quote for any type of crane in order to keep their place in the market.

A book on the subject intended to be of any real use to designers must, therefore, deal with special cranes as well as with cranes of the ordinary type, and the matter must be presented in a sort of tabloid form arranged in such a way that the information required for the work in hand can be obtained without loss of time. Another difficulty which the writer of a book on electric crane construction has to face arises from the fact that crane designers are generally mechanical engineers with but an elementary knowledge of electrical engineering. This is to be deplored, and we hope that during the next decade the profession will be strengthened by a strong body of electro-mechanical draughtsmen. In the meantime it behoves writers of books on mechanical engineering subjects to make matters electrical as simple as possible.

Of the books on cranes which are available, many are, in the main, merely a collection of half-tone pictures, and badly-drawn illustrations combined with the necessary amount of padding culled from trade catalogues. The book under review is not of this kind. From an examination of the contents it appears that an attempt has been made to deal with the question of crane design from a scientific standpoint.

For purposes of review it will be best to divide the book into three sections. The first seven chapters deal with the principal types of crane. Chapters VIII. to XVII. deal with design, and Chapter XVIII. is devoted to the description of crane installations.

The first seven chapters, and the last chapter, are entirely sketchy, and it is doubtful whether, in a book of this kind, they serve any really useful purpose. The chapter on Overhead Cranes is most incomplete. There is still a demand for monomotor cranes, and for small capacity cranes having power-driven lifting mechanism and hand traversing and travelling mechanisms. Since cranes of the overhead-travelling type are the most widely used, it might reasonably be expected to find descriptions and drawings of the principal forms. But only the ordinary multi-motor crane is described, and much very important matter is omitted. A day or two ago the reviewer desired to know the probable weight and constants of a 40-ton three-motor crane of 50-ft. span. On turning to the book under review he found no mention of the weights of overhead cranes. With equal want of success he referred to the next chapter for the probable weight of a 5-ton low-truck portable jib crane of 40-ft. radius. In giving an approximate price and in many other ways, such information, in a convenient form, is invaluable.

In the chapter on Jib Cranes the author describes three cranes, namely: a 3-ton loco. crane, a 2½-ton portable crane,

Digitized by Google

and a 4-ton harbour crane. It is well known that for discharging general cargo jib cranes provided with free-barrel lifting mechanism are in great demand, and it is equally well known that in engineering shops, where an ordinary crane service cannot be provided, mono-rail jib cranes have been used with conspicuous success. Moreover, jib cranes fitted with the Mitchell-Williams compensated derricking gear are rapidly coming to the front, and engineers are turning their attention to electric coaling cranes. None of these are mentioned. This laxity is common to other sections of the book. In vain will the reader look for descriptions of the many special cranes used in steel works, in shipyards and in stockyards. The absence of such information leads one to the conclusion that the author has given insufficient time to the preparation of the book.

Turning now to the part of the book which deals with design, the methods of determining the power required for crane driving are first described, and the analyses taken from test figures are good. For rapidly estimating the power required for lifting it is sufficiently accurate, in cranes of small and medium capacity, to multiply the load in tons by the speed in feet per minute and divide by 10; symbolically, B.H.P. = WS/10. Somewhat fuller treatment of the section on slewing would have been welcome. Thoughtful designers will read and re-read the chapter on starting torque and acceleration, and the many examples add materially to the value of the chapter.

Much of the elementary matter relating to struts and columns in the chapter on the Design of Crane Structures is rather out of place, for in books on Applied Mechanics and on Structures full discussions are already to be found. More examples on the design of struts would have been helpful. The section on girders is well written, and the examples are particularly good. In future editions it would, perhaps, be an advantage to describe the type of bridge much used for overhead cranes. This type consists of two single web plate girders braced to outrigger lattice girders. It gives a very rigid construction and is economical of material. A further advantage is that all parts are accessible for inspection and painting.

Chapters XI. to XIV. are devoted to the design of machinery and separate chapters are given to important details, such as brakes, gearing and so forth. Constructional details of worm gears would have added to the value of the chapter on gearing, as also would a table of strengths of wheel teeth, but the author's treatment of the subject is admirable, and will be of real use to designers. For very heavy cranes, hydraulic brakes cannot be improved upon, and a description of such a brake should have been included. It is unfortunate that certain important details such as pitch chains, transmission chains, clutches, ball bearings and motion screws are not considered.

Of the chapters on Electric Equipment those dealing with motors and controllers are praiseworthy. A chapter on Crane Wiring Diagrams would have appealed to many engineers. Differences of opinion exist on the value of model specifications in a work of reference, but there can be no doubt that such specifications are of great assistance to makers and users, and the book would have been improved by including specifications of the special cranes which are not described in the text.

We reiterate, that in a book intended to be of maximum use to engineers it is necessary to deal with special cranes. To find no such cranes described in an expensive book is certainly a sin of omission.

Das Kristallisationsmikroscop und die damit gemachten Endeckungen insbesondere die der flüssigen Kristalle. By Dr. O. LEHMANN. (Braunschweig: Vieweg & Son.) Pp. 112. M.3 net.

This book is a summary of the author's researches on crystalisation phenomena with the help of the microscope. Dr. Lehmann, who has been working on the subject for nearly 40 years, has certainly been a pioneer in the field, and in writing this book he has evidently wished to maintain his right of priority, especially in connection with the discovery of so-called "liquid crystals." Considerable space is devoted to a rather tedious argument on this question, and it is pointed out that the results of scientific research are apt to be readily taken as common knowledge without due credit being given to their authors. Dr. Lehmann suggests that text-books and similar works should be more strictly annotated with references to original publications. The present work certainly fulfils this requirement, as there are in the text over 150 references which should prove useful to those wishing to investigate the subject fully.

Attention is drawn to the growing importance of a chemical microscope arranged so that crystals can be examined as they separate and grow from solution, or as they solidify from a fused substance, and the practical use of such an instrument for analytical work is pointed out. In describing the development of his own instrument the author leads to a description of the most modern chemical microscopes. This part of the book is excellently illustrated, and gives details of arrangements, hitherto unpublished, for thermal measurements of the specimens, while methods of heating, lighting and photographing the objects are also dealt with.

The discoveries made by Lehmann with his instrument are fully treated in others of his works, and are only briefly surveyed in this book. The nature of the anomalous mixed, plastic and liquid crystals observed by him and others is considered, and the theoretical importance of their existence is discussed. It must be admitted, however, that these considerations prove rather unsatisfactory on account of their controversial nature, and the necessary scantiness of their treatment. Dr. Lehmann has striven to detect a link between inorganic matter and the lower organisms, and has made himself the centre for fierce criticism. The view that the solid, liquid and gaseous states of matter are all polymorphous modifications similar to those already recognised is also voiced.

A valuable asset is provided in the form of a long list of demonstration experiments serving to illustrate the various phenomena described.

Encyclopédie Electrotechnique. Part 48: ESSAIS DES MACHINES A COURANTS ALTERNATIFS. By G. FERROUX. (Paris, 1911: L. Geisler.) Pp. 184. Fr. 2·50.

This part of the encyclopædia forms in itself a useful little book on the testing of alternating-current machines. It gives a fairly complete description of the various tests in common use, and also goes at some length into such parts of the theory of the machines as are in use in working out the test results. For instance, the various methods in use for predetermining the full load excitation of alternators from a knowledge of the open and short-circuit characteristics are fully given: the Heyland diagram for induction motors is also discussed at some length.

Our chief criticism is that but little attention is paid to heating tests of alternators. Most firms at the present day make use of the Mordey or Behrend test, or one of its modifications, and it is to be regretted that the author has not included such tests in his work. The Hopkinson differential test is one that is sometimes used when two similar machines are available, and might well have been mentioned.

There are nine chapters in all. The first deals in a general manner with alternating-current measurements. The next three are devoted to alternators. The magnetic study and determination of the electrical characteristics are well treated: but the use of the oscillograph might well have been mentioned. The author too has overlooked the use of an under-excited synchronous motor in the testing of alternators on dead load.

Chapters V. and VI. give a very full treatment of the testing of transformers. A full description of the predetermination of the pressure regulation is given, and also of the various differential tests for two similar transformers.

The next chapter contains all that is necessary on the testing of synchronous motors. The testing of polyphase induction motors is also very thoroughly discussed. The method commonly used to determine the efficiency of large motors, *i.e.*, by loading them on a generator of known efficiency, might have been mentioned. The subject-matter is concluded with a short chapter on rotary converters and single-phase commutator motors.

There are but few typographical errors; the work is carefully written, and the diagrams, of which there are some one hundred and twenty, are clear. The book would be of use to all those who have to deal with the testing of alternating-current machinery, and for 2fr. 50c. it is a good investment.

TURIN MEETING OF THE INTERNATIONAL ELECTROTECHNICAL COMMISSION.

At Turin, Italy, on Thursday, September 7th, Col. R. E. Crompton, C.B., the Honorary Secretary, declared open the first plenary session of the International Electrotechnical Commission. The meetings, which were held in the Palace of the Prefecture of Turin, kindly placed at the disposal of the Commission by the Provincial Council, consisted of a first plenary meeting, presided over by Prof. Elihu Thomson (U.S.A.), the then President of the Commission, two all-day unofficial meetings presided over by Prof. Luigi Lombardi, President of the Italian Committee, a second plenary meeting to consider and formally adopt the recommendations of the unofficial meetings and, finally, a meeting of Council to consider matters of finance and internal organisation. The Council Chamber, although somewhat magnificent, was at the same time so comfortably arranged as to make somewhat bearable the intense heat which prevailed during the greater part of the sittings.

Nineteen different countries were represented by 52 delegates, amongst whom were the official delegates of the British Government, Mr. Alexander Siemens, Major W. A. J. O'Meara, C.M.G., and Dr. Silvanus Thompson (Dr. R. T. Glazebrook, C.B., was also a Government delegate, but was unable to attend), and the official delegate of the Indian Government, Mr. J. W. Meares. His Excellency Signor T. Calissano, the Italian Minister of Posts and Telegraphs, on behalf of his Government extended a very warm welcome to the Commission, which he likened to a world's parliament of electricians.

Prof. Elihu Thomson in thanking His Excellency, in the name of the Commission, for his courteous welcome given in French, felt bound to use the same language in reply, which he did in a most able manner. Prof. Thomson then followed with his presidential address, and commenced by alluding to the profound influence of Italian genius upon the philosophy, science and art of the world, as exemplified by the immortal works of such men as St. Thomas d'Aquinus, Dante, Michael Angelo, Galileo and Leonardo da Vinci. He paid homage to those pioneers, Galvani and Volta, Galileo Ferraris, and Antonio Paccinotti, the last mentioned of whom the members had the pleasure of meeting at a special session arranged for the purpose, when an illuminated album was presented to him amidst much enthusiasm.

Prof. Thomson offered to the Italian nation on the fiftieth anniversary of its union, the most sincere congratulations of the Commission. He also complimented the various Local Committees upon their excellent work and more especially thanked them for their splendid co-operation with the Central Office. The delegates, he said, were no longer strangers, but comrades. He suggested the formation of several small International Committees so as to give the Local Sections a closer interest in the actual preparation of the work, and this suggestion was acted upon later. In closing his interesting address, of which the above is scarcely more than an epitome, Prof. Thomson, as the retiring President, expressed his deep appreciation of the honour conferred upon him by the members in having elected him as their President in 1908 and he thanked them most heartily for this evidence of their confidence.

Prof. Dr. Budde proposed a vote of thanks to Prof. Thomson, which was carried by acclamation.

Col. Crompton next gave a short report on the general progress made. He said that whereas in 1908 there were only 10 countries joining in the work, there were now 21 in which an Electrotechnical Committee was properly constituted, in most cases with the direct assistance of the respective Governments.

PHOTOGRAPH, TAKEN AT TURIN, OF THE DELEGATES AND OTHERS PRESENT AT THE RECENT MEETING OF THE INTERNATIONAL ELECTROTECHNICAL COMMISSION.

FRONT ROW.
1. His Excellency T. Calissano, Italian Minister of Posts and Telegraphs.
2. Prof. Dr. E. Budde, President of the I.E.C.
3. Prof. Elihu Thomson (U.S.A.), Retiring President.

SECOND ROW.
1. M. Emanuele Jona. (Italy).
2. Senator Vittorelli, Prefect of the Province.
3. M. de Chatêlain (Russia).
4. Prof. Luigi Lombardi (President, Italian Committee).
5. Prof. Absolon Larsen (Denmark).
6. M. R. V. Picou (President, French Committee).
7. Col. R. E. Crompton, C.B. (Hon. Sec. I.E.C.)
8. Prof. Dr. K. Strecker (Germany).
9. Mr. Alexander Siemens (President, British Committee, and Government Delegate).
10. M. Atsushi Oya (Japan).
11. M. E. Brunswick (France).
12. M. C. le Maistre (General Secretary I.E.C.).
13. M. Ch. David (Secretary French Committee.)
14. Signor Carlo Clerici (Italy).

THIRD ROW.
15. Major W. A. J. O'Meara, C.M.G. (Great Britain and Government Delegate).
16. Mr. Gano Dunn (U.S.A.), President A.I.E.E. and Government Delegate.
17. Mr. Leon Gaster (personally invited to attend).
18. Prof. Clarence Feldmann (President, Dutch Committee).
19. Mr. S. Faber (Denmark).
20. M. Paul Boucherot (France).
21. M. J. Blondin (France).
22. Dr. Silvanus P. Thompson (Great Britain. Government Delegate).
23. M. Blondin, fils (France).
24. M. O. De Bast (Secretary, Belgium Committee).
25. M. E. Gevaert (Belgium), behind Dr. Strecker.
26. Mr. C. O. Mailloux (President, United States Committee and Government Delegate).
27. Prof. Guido Grassi (Italy).
28. Prof. E. Morelli (Italy).
29. Comm. G. Duran (Rep. Italian Posts and Telegraphs).
30. Senor R. Muller (Ecuador).

FOURTH ROW.
31. Prof. Dr. Moritz de Hoor-Temres (Hungary).
32. Herr Georg Dettmar (Secretary, German Committee).
33. Prof. T. Mather (Great Britain).
34. Herr K. Tauber (Switzerland).
35. Senor Alfonso Castello (Mexico).
36. Prof. J. Landry (Secretary Swiss Committee).
37. Señor Luis de la Peña y Braña (Spain).
38. M. G. A. L'Hoest (Belgium).
39. M. H. Armagnat (France).
40. Dr. A. E. Kennelly (Secretary, U.S.A. Committee).
41. Dr. Clayton Sharp (U.S.A.)
42. Heer L. M. Barnet Lyon (Holland).
43. Mr. P. F. Rowell (Secretary, British Committee).
44. Signor Guido Semenza (Secretary, Italian Committee).

BACK ROW.
45. Mr. C. Ericson (Secretary, Swedish Committee).
46. Mr. C. A. Rossander (President, Swedish Committee).
47. Reporter (French).
48. Reporter, J. Perrott (English).
49. Mr. E. L. Litton (Assistant).
50. Mr. R. K. Gray (Great Britain).
51. Mr. G. A. Bona (Panama).

Prof. L. W. Gill (Canada).
Mr. J. W. Meares (British Indian Government).
The Portuguese Consul.

Having touched upon the various subjects under discussion, he reported what he considered a most valuable instance of co-operation and one which would, at any rate, be of great assistance to the British Section of the Commission. Through the good offices of Mr. Alexander Siemens, President of the British Committee, the British Engineering Standards Committee had been invited to and had appointed a joint Committee to deal with all electrical matters from the international point of view. The Committee would consist of members of the British Local Committee and of the Electrical Section of the Engineering Standards Committee, in addition to the usual Government representatives. This desire to co-operate for the good of the community, he felt sure the members would agree with him, was worthy of all praise.

The election of officers was then proceeded with and M. R. V. Picou, President of the French Committee, in a most charmingly courteous speech, proposed that Dr. Budde be elected to succeed Prof. Elihu Thomson. He said that, as everyone knew, Dr. Budde had taken the keenest interest in the Commission from its very inception; he was a great worker and his active assistance had been of immense advantage to the movement. Quite recently, in the matter of the symbols for Ohm's law, he had obtained from his compatriots the necessary sacrifice which had made international agreement possible. Finally, the leading part Dr. Budde had taken in the question of technical nomenclature and which had contributed in such a large degree towards a practical solution, rendered the Commission even more indebted to him. M. Picou, therefore, had the greatest confidence in proposing that, as a respectful homage to him for services already rendered, Prof. Dr. Budde be elected President of the Commission, and he felt that this election would be of the greatest benefit to the Commission as a whole. This proposal was seconded by Mr. C. A. Rossander, President of the Swedish Committee, and carried by acclamation, members rising in their seats.

Dr. Budde thanked the members for the honour they had done him and said he would do all in his power to further the aims and objects of the Commission.

Prof. Feldmann (Holland) said there were many present at this meeting who would remember the St. Louis Congress of 1904, where Col. Crompton had developed the idea of international co-operation in matters electrical. He was, in fact, the father of the I.E.C., and it was, therefore, with the greatest pleasure that he proposed the re-election of Col. Crompton as Honorary Secretary of the Commission. This was enthusiastically seconded by Prof. Lombardi (Italy) and carried by acclamation, members again rising in their seats.

Col. Crompton having expressed his thanks, on the proposal of Mr. Siemens, seconded by Mr. Faber (Denmark), it was carried unanimously that Prof. Lombardi be elected to preside over the unofficial meetings to be held.

The Minister of Posts and Telegaphs kindly consented to despatch a congratulatory telegram to His Majesty the King of Italy on behalf of the Commission. The meeting then adjourned and the members went into the Royal Gardens where the photograph here reproduced was taken, the list of names being given below.

The following morning at 9 a.m. Prof. Lombardi opened the unofficial meetings, the agenda for which had been in circulation amongst the various Committees for some months previously. The first question was that of nomenclature, and on behalf of the small Committee appointed at Brussels Dr. Budde presented a short report showing the work accomplished. He referred to the meeting held at Cologne in May last and stated that the modifications to the Cologne report which had been sent in by various National Committees had been given the most careful attention at a meeting held in Turin just before the present sitting of the Commission. He presented the result of this work in French and English. Some criticism at first arose as to the procedure adopted in this work, but after some discussion and explanations the report was adopted under the title "List of Terms and Definitions in the Official Languages, French and English, provisionally adopted by the I.E.C."

It was explained that the word "provisionally" was intended to imply that, at the next meeting, in two years' time, if it was found really necessary, modifications to the definitions would be considered. The List is to be published arranged in two methods, the one alphabetical, the other the logical order of sequence of ideas. The small International Committee consisting of one representative of France, Germany and Great Britain remains in being for two years, and Prof. Larsen (Denmark) is specially invited to attend the meetings. In view of the importance of the Spanish language the Spanish Committee is invited to send a delegate to follow the work; the Committee as originally appointed being alone empowered to vote.

An obviously necessary proposal was adopted that the National Committees be at liberty, and be invited to send delegates to attend the meetings of any and all special Committees.

The French Committee, through their President, M. R. V. Picou, presented their complete vocabulary in French, including a most useful affiliation table of the terms drawn up by Mr. P. Boucherot. Other Committees also presented their work on nomenclature.

The next question discussed was that of symbols, with the Brussels propositions as a basis. These, with small modifications as to form, were agreed to provisionally. The question as to the use of any particular type to represent magnetic quantities was left open. The following are the resolutions:—

1. Instantaneous values of electrical quantities which vary with the time to be represented by small letters.

2. Virtual or constant values of electrical quantities to be represented by capital letters.

3. Maximum values of periodic electrical quantities to be represented by capital letters followed by the subscript *m*.

4. Magnetic quantities, constant or variable, to be represented either by capital script, Gothic, heavy faced or any special type.

5. Maximum values of magnetic quantities to be represented either by capital script, Gothic, heavy faced any or special type followed by the subscript *m*.

6. The following quantities to be represented by the following letters:—

Electromotive force	E, *e*	
Electric quantity	Q, *q*	
Inductance*	L	See resolutions 4 and 5
Magnetic force	H	
Magnetic flux density	B	

Mass	M, *m*.
Length	L, *l*.
Time	T, *t*.

The letters I. E. R. were, on the proposition of Dr. Budde, seconded by Mr. Siemens, unanimously agreed to for the respective quantities in the simple representation of Ohm's law.

The term "reactive power" was also adopted to designate the quantity $V I \sin \phi$.

A special Committee consisting of one member from Belgium, France, Germany, Great Britain, Holland, Italy, Spain, Switzerland, and U.S.A., was appointed to continue the study of the international unification of symbols, and some additional propositions put in by the French as well as certain other suggestions by the Dutch, were referred to this Committee to be dealt with.

The good work of the A.E.F., the Pan-German Committee on symbols of the Elektrotechnischer Verein, of which Dr. Strecker is the able President, and which has done so much during the past 10 years towards the adoption of international symbols, was fully recognised by all present, and it is confidently hoped that, through the intermediary of the German Local Committee, the I.E.C. will enjoy the full benefit and advantage of the active co-operation of this important Association in the difficult subject of symbols generally.

The vexed question of the graphical representation of alternating-current quantities did not give rise to anything like the amount of discussion anticipated, and the following proposition

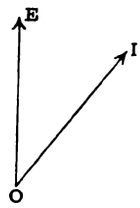
* Coefficient of self-induction.

Digitized by Google

was agreed to without any difficulty whatever, beyond a question as to the utility of the note added by way of explanation:

In the graphical representation of alternating electric and magnetic quantities advance in phase shall be represented in the counter clockwise direction.

NOTE.—In consequence, the impedance of a reactive coil of resistance R and inductance L is $R + \sqrt{-1}L\omega$ and that of a condenser of capacity C is $\frac{1}{\sqrt{-1}C\omega}$, where ω is equal to $2\pi \times$ frequency. It follows also that the diagram herewith represents the phase relations in a simple alternating-current circuit containing an impressed E.M.F., O E, and a lagging current O I.



The rating of electrical machinery received detailed attention and not only were the three propositions referring to the rating of generators and motors in international watts put forward at Brussels adopted, but a Committee consisting of representatives from Belgium, France, Germany, Great Britain, Italy, Switzerland, Sweden and U.S.A., was appointed to study the subject from the international point of view. The work already carried out in various countries in reference to the rating of machinery was fully appreciated, and, through the National Committees, the co-operation of those bodies who have made it their business to study this particular problem is to be sought.

An interesting report on the question of prime movers for electrical purposes was presented to the Commission on behalf of the Italian Committee by Mr. E. Jona, and this was referred to the small Committee with instructions to give it their most careful attention.

A report on the different Standard Rules extant, prepared by the Central Office, was also referred to this Committee with a view to assisting its labours. This completed the definite work which had been before the National Committees during the past year and upon which decisions were desired. Mr. Leon Gaster, personally invited to attend as representative of the Illuminating Engineering Society of London, at the invitation of the President made a few remarks on the question of the nomenclature of illumination. Dr. Kennelly, President of the American Society of Illuminating Engineers, and Dr. Clayton Sharp, a past-President, also spoke on the subject and of its importance to the I.E.C. now that the question of electrical nomenclature generally was under consideration. The members, after a brief discussion, expressed themselves in favour of the idea of the National Committees communicating upon the subject with the Societies in their respective countries dealing with these matters.

The I.E.C. has decided to meet at Berlin in 1913, the exact date being decided later. The I.E.C. has also accepted the invitation of the American Institute of Electrical Engineers, so cordially presented by Mr. Gano Dunn, its new President, to hold a plenary meeting at San Francisco in 1915 on the occasion of the Great Exhibition to celebrate the opening of the Panama canal.

At the official request of the International Congress of the Applications of Electricity, the Council of the I.E.C. has decided, subject to the ratification of the Local Committees, to accept the task of organising all future Electrotechnical Congresses. It has also accepted the invitation transmitted through the American Local Committee in reference to an International Electrotechnical Congress at San Francisco in 1915.

At the second plenary meeting held on Monday, September 11th, the report of the work of the unofficial meetings was received and decisions officially adopted in the sense already outlined.

A council meeting was held on Wednesday, September 13th, at which the request of the Electrical Congress of Turin was discussed with the result above indicated. In addition to this important matter, questions of finance and internal organisation were dealt with.

Finally votes of thanks to the presiding officers, to M. Mailloux for his invaluable assistance in translating the speeches, and to the officers of the Commission, concluded the proceedings, which were voted by one and all a complete success. In view of the above report we feel sure our readers will share this opinion.

THE SINGLE-PHASE REPULSION MOTOR.*

BY THOMAS F. WALL, M.SC., M.ENG.

(*Continued from page* 923.)

Summary.—In the first part of this Paper expressions are deduced for the E.M.F.s induced in the stator and rotor windings, and curves are given which enable some of these E.M.F.s to be rapidly determined for any value of the displacement of the rotor brushes from the stator axis. In the second part of the Paper the results previously obtained are employed in developing the theory of the repulsion motor. A series of simultaneous equations enable expressions to be obtained for the speed, stator current, power factor and power of the motor. In the third part of the Paper the results of some tests on a 6 B.H.P. motor are given, and the values of the stator current, power factor and speed are shown to be in agreement with the theory. Finally, a method of calculating the open circuit characteristic of a single-phase motor is given.

PART II.

In order to present the method with the greatest possible clearness we shall neglect in the first place the resistance of the rotor winding, the resistance of the stator winding, the leakage of the rotor winding, and the leakage of the stator winding. The general case will then be examined and the effect of these different quantities on the final result will be ascertained.

If a current be passed through the stator winding, a flux will be produced which will be directly proportional to the current (if the limits of saturation be not exceeded). This flux will link both stator and rotor windings, the flux linkages being in each case the sum of the products—flux × number of coils linked—taken for all the coils. Similarly, if a current be passed through the rotor winding a flux will

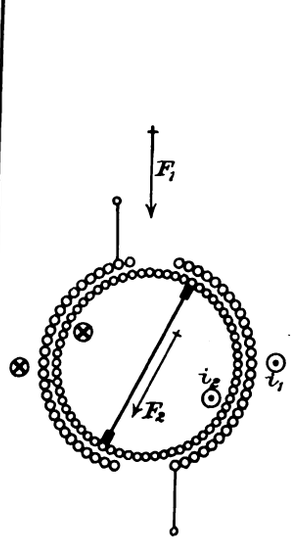


FIG. 10.

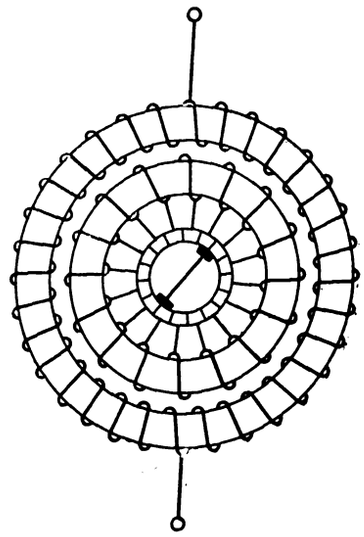

FIG. 11.

be produced which will be directly proportional to the current, and the flux linkages in this case also will be represented for both stator and rotor windings by the sum of the products—flux × number of coils linked.

For any given simultaneous values of the currents in the stator and rotor windings respectively, the flux linkages for both the stator and rotor windings will be simply the algebraical sum of the values of the flux linkages for each current.

Suppose the current in the rotor winding at any instant to be i_2 amperes. The flux distribution in the air-gap will be as shown in Fig. 8, for a smooth-cored armature and an indefinitely large number of conductors in the rotor winding.

The number of ampere-turns per pair of poles will be

$$= \frac{Z_2 i_2}{2P p_{2r}},$$

Z_2, P, p_{2r} having their previous signification. But the ampere-turns per pair of poles are $= 1{\cdot}6 B_{max} \delta$, in which δ is the length of the air-gap in centimetres. This expression holds for the case of smooth-cored rotor and stator. For slotted cores, the ampere-turns per pair of poles are $= 1{\cdot}6 k_1 B_{max} \delta$, in which k_1 is a coefficient which takes account of the fact that the maximum flux density over any small strip, measured in the direction of the circumference of the air-gap, is greater than the mean value (*cf.* previous references).

* Paper read before Section G of the British Association at Portsmouth.

Digitized by Google

We may therefore write

$$\frac{Z_2 i_2}{2Pp_{2r}} = 1{\cdot}6k_1 B_{max.}\delta$$

or $$B_{max.} = \frac{Z_2 i_2}{2Pp_{2r}1{\cdot}6k_1\delta}$$

or $$B_{max.} = A_2 i_2,$$

A_2 being a constant of the machine and $= \frac{Z_2}{2Pp_{2r}1{\cdot}6k_1\delta}$.

Now, it has already been shown that the flux linkages of the rotor winding due to a current in that winding are

$$L''_R = \frac{B_{max.} lw_2 r^2 \pi^2}{3Pp_{2r}}$$

or $$L''_R = C_2 B_{max.},$$

in which $$C_2 = \frac{1}{3Pp_{2r}} lw_2 r^2 \pi^2,$$

and is a constant of the machine.

$$\therefore\ L''_R = A_2 C_2 i_2.$$

Again, the flux linkages of the rotor winding due to a current in the stator winding is (equation (2A) and Fig. 4)

$$L'_R = \frac{1}{3Pp_{2r}} B_{max.} lw_2 r^2 \theta_C$$

or $$L'_R = C_1 B_{max.},$$

in which $C_1 = \frac{1}{3Pp_{2r}} lw_2 r^2 \theta_C$, and is a constant of the machine for any given angle θ.

Now, $B_{max.}$ can be expressed as above in terms of the current i_1 in the stator winding, viz., $B_{max} = A_1 i_1$, in which $A_1 = \frac{Z_1}{2Pp_{2s}1{\cdot}6k_1\delta}$, and is a constant of the machine. Hence, the resultant flux linkages of the rotor winding for any current i_1 in the stator winding and any current i_2 in the rotor winding is

$$L_R = L'_R + L''_R = A_1 C_1 i_1 + A_2 C_2 i_2. \quad . \quad . \quad . \quad . \quad . \quad (6)$$

In order to avoid confusion it is desirable to agree upon a convention as to the meaning of positive and negative values of the flux linkages.

In Fig. 10 a current, i_1, in the stator winding flowing in the direction shown by the (⊗) and ⊙ is assumed to be positive, and produces a flux in the direction shown by F_1. The flux linkages of the stator and rotor windings respectively due to this current are taken as positive. A current, i_2, in the rotor winding flowing in the direction shown by the (⊗) and ⊙ is assumed to be positive, and produces a flux in the direction shown by F_2. The flux linkages of the stator and rotor windings respectively due to this current will also be positive.

For the flux linkages of the stator we may proceed in a similar manner.

The flux linkages of the stator winding due to any current i_1 in the stator winding is (equation 1A)

$$L'_s = A_1 D_1 i_1,$$

in which $D_1 = \frac{1}{3Pp_{2s}} lw_1 r^2(\pi - 2a)(\pi + 4a)$ and is a constant of the machine.

The flux linkages of the stator winding due to any current i_2 in the rotor winding is (equation 4A), $L''_s = A_2 D_2 i_2$, in which $D_2 = \frac{1}{Pp_{2s}} lw_1 r^2 \theta_D$ and is a constant of the machine.

Hence the resultant flux linkages of the stator winding for any current i_1 in the stator coils and any current i_2 in the rotor coils is

$$L_s = L'_s + L''_s = A_1 D_1 i_1 + A_2 D_2 i_2. \quad . \quad . \quad . \quad . \quad . \quad (7)$$

Expressions (6) and (7) allow the stator linkages to be immediately determined for any values of i_1 and i_2.

Now, if a sine wave form of pressure be applied to the stator terminals it at once follows that the stator flux linkages must vary as a cosine function of the time, and may be represented by the expression

$$L_s = L_{s\ max.} \cos 2\pi\nu t$$

for any time t, in which ν represents the frequency of the applied pressure and $L_{s\ max.}$ the maximum value of flux linkages. Since for the present the resistance and leakage of the stator winding are neglected we may write

$$L_{s\ max.}\ 4{\cdot}44\nu 10^{-8} = P,$$

P being the effective value of the applied pressure in volts.

$$\therefore\ L_s = \frac{P10^8}{4{\cdot}44\nu} \cos 2\pi\nu t.$$

Further, since the resistance and leakage of the rotor winding are for the present neglected, it follows that the E.M.F. induced in the rotor winding due to the pulsation of the rotor-flux linkages must be at every instant equal in magnitude and of opposite sign to the E.M.F. due to the rotation of the rotor winding in the field produced by the current i_1 in the stator winding, for it is evident that it is only the flux due to the stator current i_1 which can produce an E.M.F. of rotation in the rotor winding. It follows then that when i_1 is zero, the E.M.F. of rotation will be zero, and hence the E.M.F. of pulsation of the rotor linkages L_R must be zero when i_1 is zero. Hence, dL_R/dt must be zero when i_1 is zero—*i.e.*, L_R must be a maximum (as regards magnitude) when i_1 is zero. Therefore L_R and i_1 must be displaced relatively to each other by 90 deg. in time. In order to ascertain what sign must be given to L_R when i_1 is zero, we may consider the following: Referring to Fig. 11 it will be seen that when the short-circuited brushes are turned in a clockwise direction out of the stator axis the rotation will also be clockwise.* When the stator current is positive the E.M.F. of rotation, when the rotor turns in a clockwise direction, will also be positive. Hence, the E.M.F. of rotation in the rotor winding and the stator current are co-phasal, and therefore since the E.M.F. of pulsation of L_R in the rotor winding must balance the E.M.F. of rotation, L_R itself must be 90 deg. behind the stator current (since the E.M.F. dL_R/dt is 90 deg. behind L_R).

Fig. 12 gives the relative phase displacements of the different quantities for the ideal case of no resistance or leakage, and $\theta = 0{\cdot}2\pi$, $\nu = 50$, the speed n being assumed to be 1,000 r.p.m.

Now, let t_1 be the time at which the stator current passes through zero (from a positive to a negative direction). Then, since at the time $t = 0$, L_s has a maximum positive value, and the applied pressure at the stator terminals must be passing through zero from a positive to a negative value; *hence $2\pi\nu t_1$ will be the angle of lag ϕ of the stator current behind the applied pressure.*

Flux Linkage scale for L_S.	*Amps. scale for i_1.*	*Amps. scale for i_2.*	*Flux Linkages scale for L_R.*	*Scale for P. Volts*
$0{\cdot}5\cdot10^8$	50	100		100

* If the brush-axis is perpendicular to the stator-axis when the motor is at rest, a movement of the brushes in a counter-clockwise direction causes the rotor to revolve in a clockwise direction.

Digitized by Google

Further, since the stator current is zero at the time t_1 and is passing from a positive to a negative direction, the stator current must reach its maximum positive value at a quarter of a period earlier than the time t_1, that is to say, at the time $t_1 - 1/4\nu$, where ν represents the frequency of the supply (and consequently also the frequency of the current in the rotor circuit).

Let $\bar{I}_1$ represent the maximum value of the stator current.

The first part of the problem then resolves itself into a determination of the value of $\bar{I}_1$ and t_1. For, knowing the supply pressure, we shall have obtained both the magnitude and phase relationship of the stator current for all speeds, and we can thus draw the current diagram of the machine. It will then be shown how the performance of the motor may be accurately determined from the diagram as regards speed, torque and power.

From expression (3) we have: The maximum pressure due to the rotation of the rotor winding is

$$\bar{V} = \frac{1}{15 p_{2_r}} B_{max.} Z_2 n r l \pi \frac{\theta - \theta^2 - \alpha^2}{\pi - 2\alpha} 10^{-8} \text{ volts}$$

$$= E\bar{B}_{max.} n,$$

where $$E = \frac{1}{15 p_{2_r}} Z_2 r l \frac{\pi\theta - \theta^2 - \alpha^2}{-2\alpha} 10^{-8}.$$

But $$B_{max.} = A_1 i_1$$

$$\therefore \quad v = EA_1 i_1 n \text{ volts.} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (8)$$

v being used to denote the instantaneous value of the E.M.F. of rotation.

The equations which must be satisfied are

$$L_R = A_1 C_1 i_1 + A_2 C_2 i_2,$$

$$L_s = A_1 D_1 i_1 + A_2 D_2 i_2,$$

$$L_s = \frac{P 10^8}{4{\cdot}44\nu} \cos 2\pi\nu t,$$

$$v = \frac{dL_R}{dt} 10^{-8} = EA_1 i_1 n.$$

It has already been shown that at the time $t_1 - \frac{1}{4\nu}$, i_1 is a maximum and equal to $\bar{I}_1$ and L_R is zero.

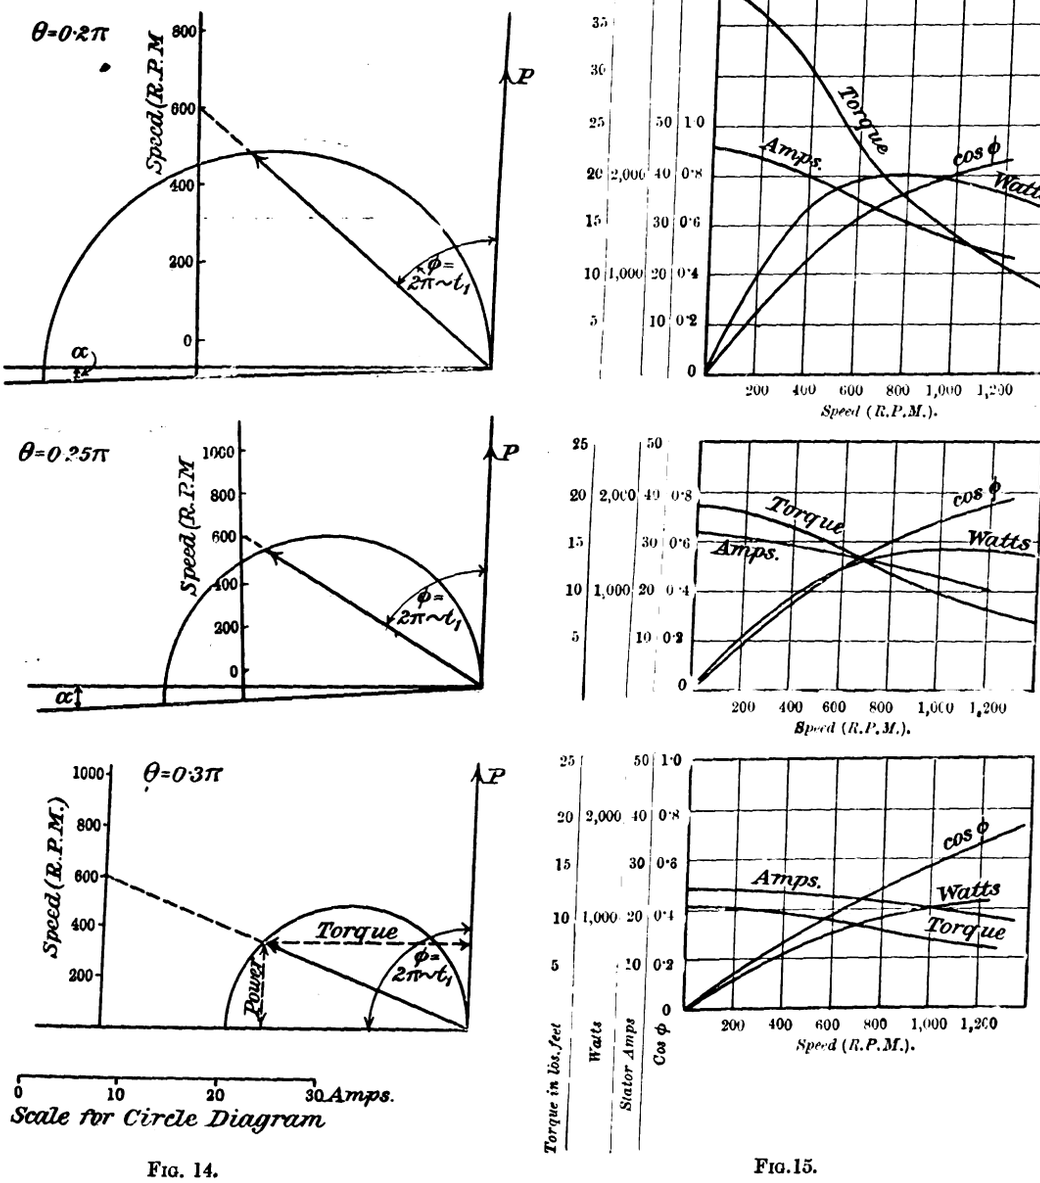

FIG. 14. FIG. 15.

Hence we may write for the time $t = t_1 - \frac{1}{4\nu}$

$$0 = A_1 C_1 \bar{I}_1 + A_2 C_2 i_2, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (9)$$

$$L_s = A_1 D_1 \bar{I}_1 + A_2 D_2 i_2, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (10)$$

$$L_s = \frac{P 10^8}{4{\cdot}44\nu} \cos 2\pi\nu \left(t_1 - \frac{1}{4\nu}\right), \quad . \quad . \quad . \quad . \quad . \quad (11)$$

$$v = \left[\frac{dL_R}{dt}\right]_{I_R=0} 10^{-8} = EA_1 I_1 n. \quad . \quad . \quad . \quad . \quad . \quad . \quad (12)$$

Now, by reference to Fig. 12, it will be seen that L_s can be represented by the expression $L_{R\,max.} \cos 2\pi\nu(t - t_1)$, in which $L_{R\,max.}$ denotes the maximum value of L_R. For $t = t_1 - \frac{1}{4\nu}$, *i.e.*, for $L_R = 0$ and increasing in a positive direction

$$dL_R/dt = -2\pi\nu L_{R\,max.} \sin (2\pi\nu)\left(t_1 - \frac{1}{4\nu} - t_1\right)$$

$$= -2\pi\nu L_{R\,max.} \sin\left(-\frac{\pi}{2}\right)$$

$$= 2\pi\nu L_{R\,max.} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (13)$$

But $L_R = L_{R\,max.}$ and $i_1 = 0$ for the time $t = t_1$.

Digitized by Google

Let i'_2 be the rotor current at the time $t=t_1$. Then we may write for the time $t=t_1$

$$L_{R\,max.}=A_2C_2i'_2 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (14)$$

$$L'_e=\frac{P10^8}{4{\cdot}44\nu}\cos 2\pi\nu t_1=A_2D_2i'_2$$

$$\therefore\quad i'_2=\frac{P10^8}{4{\cdot}44\nu A_2D_2}\cos 2\pi\nu t_1. \quad . \quad . \quad . \quad . \quad . \quad . \quad (15)$$

Hence from (13) and (14)

$$2\pi\nu A_2C_2i'_2=\frac{dL_R}{dt}\Big]_{L_R=0}. \quad . \quad . \quad . \quad . \quad . \quad (16)$$

From (12), (15) and (16) we get

$$2\pi\nu\frac{A_2C_2}{A_2D_2}\cdot\frac{P}{4{\cdot}44\nu}\cos 2\pi\nu t_1=EA_1I_1n. \quad . \quad . \quad . \quad . \quad (17)$$

From (10) and (11) we get

$$\frac{P10^8}{4{\cdot}44\nu}\sin 2\pi\nu t_1=A_2D_2i_2+A_1D_1I_1, \quad . \quad (18)$$

and from (9)

$$A_2C_2i_2=-A_1C_1\bar{I}_1. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (19)$$

From (18) and (19)

$$\frac{P10^8}{4{\cdot}44\nu}\sin 2\pi\nu t_1=A_1D_1I_1-A_2D_2\frac{A_1C_1}{A_2C_2}\bar{I}_1. \quad . \quad . \quad . \quad (20)$$

$$\therefore\quad \bar{I}_1=\frac{\dfrac{P10^8}{4{\cdot}44\nu}}{A_1D_1-\dfrac{A_1C_1D_2}{C_2}}\sin 2\pi\nu t_1. \quad . \quad . \quad . \quad . \quad (21)$$

From (17)

$$\bar{I}_1=\frac{2\pi\nu\dfrac{C_2}{D_2}\cdot\dfrac{P}{4{\cdot}44\nu}}{EA_1n}\cdot\cos 2\pi\nu t_1. \quad . \quad . \quad . \quad . \quad (22)$$

From (21) and (22) we get for the angle of lag $2\pi\nu t_1$ (usually denoted by ϕ)

$$\tan 2\pi\nu t_1=\frac{2\pi\nu(C_2D_1-C_1D_2)}{ED_2n10^8} \quad . \quad . \quad . \quad . \quad . \quad . \quad (23)$$

If we construct a diagram in which the pressure applied to the stator terminals is drawn along the ordinate axis, *the extremity of the current vector* $\bar{I}_1$ *will (according to equation* (21)*) move on a circle whose diameter lies on the abscissa axis, and has a magnitude*

$$\frac{\dfrac{P10^8}{4{\cdot}44\nu}}{\left(A_1D_1-\dfrac{A_1C_1D_2}{C_2}\right)}.$$

The circle represented by equation (21) *will be as shown in Fig.* 13.

Let any line such as CF be drawn perpendicular to the abscissa axis and let OA be any current vector. Join A to D and let B be the intersection of OA and CF. Then the triangles OBC and OAD are similar. Therefore

$$\frac{OB}{OC}=\frac{OD}{OA},$$

$$\therefore\quad OB.OA=OC.OD.$$

But OC.OD is a constant. Therefore OB.OA is a constant, say k. That is

$$I_1.OB=k.$$

$$\therefore\quad \frac{OB\cos 2\pi\nu t_1}{k}=\frac{\cos 2\pi\nu t_1}{\bar{I}_1}.$$

But from equation (22) $\dfrac{\cos 2\pi\nu t_1}{\bar{I}_1}$ is proportional to the speed n.

Therefore BC *is proportional to the speed* n.*

Since all resistances have been neglected the power of the motor must be $P.\frac{I_1}{\sqrt{2}}\cos 2\pi\nu t_1$, *i.e.*, $\frac{P}{\sqrt{2}}AM$.

Hence, the perpendicular distance from the extremity of the current vector to the abscissa axis is a measure of the power of the motor.

The torque of the motor is equal to the power divided by the angular velocity. Referring to Fig. 13, the torque is proportional to AM/BC—*i.e.*, proportional to MO/CO; and since OC is constant, *the torque of the motor is proportional to* MO, *the perpendicular distance of the extremity of the current vector from the ordinate axis.*

For a machine on which the author carried out some experiments to test the theory evolved in this Paper, it was found that the constants had the following values:—

$$A_1=183,\ A_2=89{\cdot}6,\ C_1=339\ \theta_C,\ C_2=3{,}350,$$
$$D_1=9{,}610,\ D_2=2{,}610.\theta_D,\ E=512.10^{-4}.\theta_E.$$

θ_C, θ_D and θ_E may be found for a brush displacement θ, from the curves of Figs. 5, 9 and 7 respectively.

In Fig. 14 the circles diagrams deduced from the equations (21) and (22) are shown for three different values of θ—viz., $\theta=0{\cdot}2\pi$, $0{\cdot}25\pi$, $0{\cdot}3\pi$ respectively. The applied pressure P is assumed to be 90 volts, and the frequency (ν) to be 50 cycles per second.* In Fig. 15 curves are shown which have been deduced from the circle diagrams, and show the relationship between speed and stator current, power factor, torque and power respectively, the speed having been plotted as abscissæ in each case.

(*To be continued.*)

* This may be proved at once by considering the circle of Fig 13 as the inverse of a straight line perpendicular to the abscissa axis, or, more correctly, the inverse of a straight line perpendicular to the diameter OD.

* The machine was built for 120 volts and 50 cycles, but in order to get rid of the influence of the variations of permeability of the iron the tests to be described later were made with an applied pressure P=90 volts. The curves of Figs. 14 and 15 respectively have been constructed for these values of the applied pressure and frequency, in order that they may be compared with those obtained when the resistances and leakages were not negligible.

CORRESPONDENCE.

OLYMPIA.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Would it not stimulate the visits of engineers from the provinces to this Exhibition if some arrangements could be made whereby, on some particular Saturday, half-day excursion tickets could be obtained at several of the leading provincial towns. At present, engineers in their several towns do not know what excursions are being run from other towns and do not know if they will meet engineers at the Exhibition that they would like to have an opportunity of meeting. If *some particular date*, or dates, could be arranged for such excursions, possibly many engineers might avail themselves of the opportunity and might arrange with one another to meet there.

Speaking for myself, I would have liked to have been at the Exhibition this Saturday (23rd inst.), but no excursion was running from Birmingham. I can hardly believe that if the Railway Companies were approached they would not grant special facilities for a particular date or dates, when they are continually running special excursions merely for the sake of football matches.—I am, &c.,

Birmingham, Sept. 23. ENGINEER.

A NEW SYSTEM FOR PROTECTING HIGH-TENSION CABLES.†

BY H. BIRRENBACH AND M. HÖCHSTÄDTER.

Summary.—The authors describe a new automatic protecting device for high-tension cable networks and mains invented by Mr. Hochstadter. Particulars of the installation at Cologne and the results of the tests are also referred to.

Since a previous Paper by M. Höchstädter on the "Dielectric Properties of Modern High-Tension Cables"‡ great advances have been made in Germany in the practical use of high-tension cables; thus, both the Siemens-Schuckert-Werke and Felten & Guilleaume-Lahmeyer-Werke have built and laid an asphalted lead-covered single-conductor cable for 60,000 volts alternating current. These cables were laid between the powerhouse Muldenstein and the Umformerstation Bitterfeld, a distance of about 7¼ miles, for the electrification of the main-line railway between Dessau and Bitterfeld.

Each cable of the system was tested to earth with 50,000 volts, *i.e.*, one against the other with 100,000 volts between conductors.

† Abstract of an article in the "E.T.Z."

‡ THE ELECTRICIAN, Sept. 2, 1910.

Digitized by Google

Other large cable-networks are being installed in Cologne and Barmen for working pressures of 25,000 to 30,000 volts, and it is in consequence of the importance that such cables have obtained in the electrical industry that the greatest security for good working conditions must be guaranteed.

In order to obtain this necessary security in a network of high-tension cables, that is, to be able automatically to cut out that part of the network in which a fault occurs without interrupting the supply, the Siemens-Schuckert-Werke have worked out a system which will soon be installed in Cologne.

This system resembles somewhat the Merz-Price system of the A.E.G. The secondary cable of the Merz-Price system, however, is replaced by the special design of high-tension cable in the Siemens system.

A cable network on this principle has been laid down in the suburbs of Cologne where the automatic protecting device is to be used.

When using the connections in Fig. 1 the cables have in each core, concentric to the main conductor but insulated from it and from the lead sheath, an almost closed spiral copper sheath, C_1, C_2, C_3. With

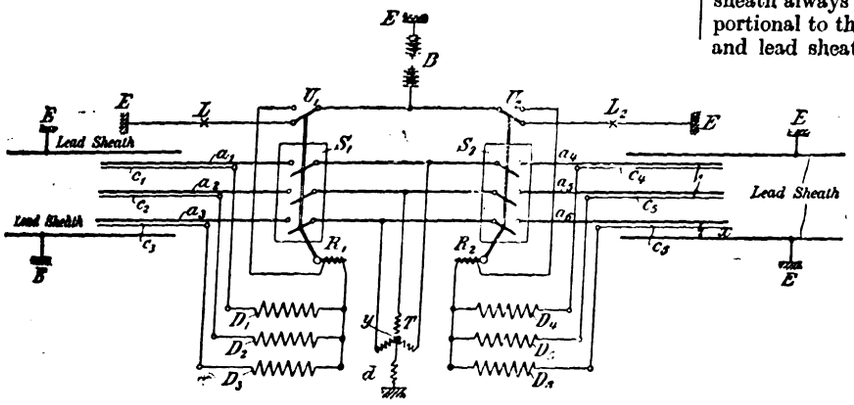

FIG. 1.—DIAGRAM OF CONNECTIONS OF ARRANGEMENT FOR CUTTING OUT FAULTY CABLE SECTION.

multi-core cables these sheaths are insulated from one another. The diagram of connections, Fig. 1, shows the arrangement in a switching chamber when using three-core cables with three-phase current. The same diagram can be used with single cables and for other current systems.

The chief point in this system is to obtain a momentary connection between the main conductor and the copper sheath, or between the latter and the lead sheath, or even between the copper sheaths themselves, by means of the spark caused by a breakdown in the insulation in any part of the cable. This is shown in the diagram at x.

In this way the circuit of a secondary battery, of which one pole is earthed, is closed through the relays R_1 and R_2 belonging to the switches S_1 and S_2 of the damaged cable, thus opening the switch.

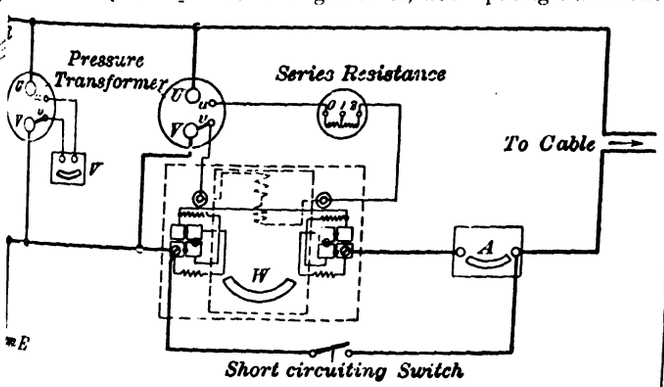

FIG. 2.—CONNECTIONS FOR THE ASTATIC WATTMETER.

The same operation occurs at the other end of the damaged cable and thus the damaged section is cut out of the network. The other switches remain closed.

In order to obtain this result with multi-core cables, in consequence of a short-circuit between two conductors, which has not affected the lead sheath, it is necessary to put one or different phases to earth, or if transformers (t) are used, the neutral point y^0 of the same, through choking coils in one or more of the switch chambers. The current from the battery then flows from the protecting sheath over the spark-gap to the conductor or conductors, and, in consequence of the earth connection, back to the battery.

In the connections between the sheaths C_1 to C_6 and the switch relays R_1, R_2, choking coils D_1 to D_6, are placed in star connection. These oppose only small ohmic resistances to the battery current, but reduce to a minimum the alternating current flowing through the relays, due to the normal voltage of the protecting sheath and also to a short-circuit, in case of breakdown.

The change-over switches U_1 and U_2 are coupled to the cable switches. The former connect the battery and the relays and operate the main switches. A signal lamp, L, is also placed in the battery circuit to show which switch in the station has operated.

The choking coils D_1 to D_6 can be built with secondary windings like testing transformers to which voltmeters are connected. These serve also to indicate the condition of the insulation of the different cable lengths, as they only show the same potential to earth when the insulation of each cable phase is equally good.

When using the above diagram with single cables, the earth at the neutral point y is not necessary, as all short-circuits must necessarily take place from the conductor to earth.

Characteristic of the arrangement in question is that the copper sheath always has a potential, relative to the working pressure, proportional to the distance between the conductor &c. copper sheath and lead sheath. This potential must be absorbed in the above-mentioned choking coils, whose star connections furnish us with a nullpoint to which the releasing coils and battery can be connected.

If one neglects the small differences of potential in the phases the releasing apparatus only have a continuous-current potential. In a normally perfect cable the copper windings have a continuous-current potential carried on the alternating-current potential.

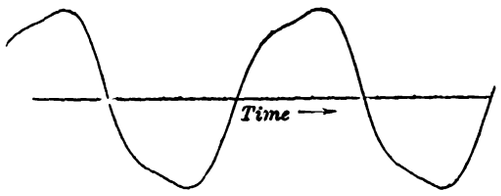

FIG. 3.—VOLTAGE CURVE.

A continuous-current battery is usually employed up to 250 volts and can be constructed of small elements which can bear a large overload and remain a long time without recharging, as the battery is usually at rest.

One of the main features of this system is that external injury to the cable—for example, piercing it with a pick-axe—cuts out that part of the system immediately, provided that the damage reaches the copper sheath.

For this reason the copper sheath is placed, in case of single cables, as near the lead sheath as possible. This makes it possible to build the choking coils with a very high factor of safety, as in single cables for high tension they have only to provide for a comparatively small part of the working pressure. And of course the apparatus for the protecting device must be so built that they themselves cannot cause any disturbance in the working of this system.

As a protection for multi-core cables against external damage an extra copper sheath under the lead sheath could be supplied. Experience shows that short-circuits seldom occur without the lead sheath being acted upon, and in this case the copper sheaths round the different cores could possibly be dispensed with.

The authors then give a description of the cable and boxes used for the Cologne network.

The cable was made in lengths of 750 m. and the weight per cable drum was about 6,500 kg. Multi-core cables can only be built in lengths of 250 m.

The size and electrical properties of the cable are as follows:—

Sectional area of copper conductor	95 sq. mm.
Diameter over lead sheath .....about	40 mm.
Diameter over asphalt covering ..... „	48 mm.
Thickness of insulation between conductor and copper sheath .....about	8 mm.
Thickness of insulation between copper and lead sheath	2·5 mm.
Total thickness of paper insulation	10·5 mm.
Radial thickness of lead sheath	3·0 mm.
Sectional area of copper sheath	26×0·07 mm.
Resistance of copper sheath .....about	30 Ω per km.
Weight of copper sheath ..... „	55 kg. per km.

The copper sheath is wound with only about 1 to 2 mm. between the spirals. It does not materially increase the price of the cable. Continuous tests have shown that the copper sheath in single, or

Digitized by Google

the three copper sheaths in three-core cables, does not affect the quality of the cable with respect to impregnating, or the resistance to bending and testing; neither does it increase the dielectric losses or the capacity insulating values.

In the end dividing box used for the above single cable the copper sheath is connected as also in the straight through joint boxes, which are cylindrical and made in bronze on account of the Foucault currents, by means of tin-foil strips.

The principal dimensions of the end box are :—

Total length	about	930 mm.
,, breadth	,,	250 mm.
,, depth	,,	250 mm.
,, length of the porcelain insulators	,,	475 mm.
Length of the projecting part of the insulators	,,	280 mm.

The authors finally give a description of the terms drawn up for the guarantee to be given for the Cologne cables and the tests which have to be fulfilled before and after laying the same.

They also describe the special astatic wattmeters which have been especially built for use with this system. Fig. 2 shows the connections employed with these wattmeters; whilst Fig. 3 illustrates a diagram taken with an oscillograph of the tension of the phases with 10,000, 15,000, and 20,000 volts.

LEGAL INTELLIGENCE.

Electrical Inspectors.

At Clerkenwell (London) Police Court on Friday an electricity supply consumer in the St. Pancras area applied to Mr. Bros for the appointment of an electrical inspector. It was stated that applicant had had a dispute with the local authority as to the kind of fuse supplied by the Council, and there was *no* one to appeal to, as St. Pancras Council (and Chelsea Electricity Supply Co.) had electric lighting powers before the L.C.C. had general powers in the matter; they were excluded from the operation of the General Act by the Local Acts, and were not subjected to the inspection of the L.C.C., as was the rest of the metropolis. The Local Acts provided that in such a case an aggrieved consumer must apply to a stipendiary to appoint an inspector and the appointment remained a permanent one. The magistrate could appoint the London County Council. Applicant was informed that neither the Board of Trade nor the County Council could take action, and was referred to the magistrate to take the initiative.

Mr. Bros adjourned the hearing of the case until Thursday, Oct. 5.

Overhead Wires in Southwark.

At Lambeth (London) Police Court on Monday Mr. Hopkins sat as arbitrator to determine a difference between the Postmaster-General and Southwark (London) Council as to overhead telegraph wires in certain thoroughfares.

Mr. P. McIntyre, for the Postmaster-General, stated that when the solicitor to the G.P.O. asked the Council to waive their objection to overhead wires the Town Clerk replied that they were unable to do so, as they were firmly opposed to the principle of allowing overhead wires. It was not proposed to use the wires for any other purpose than that of connecting up the fire-alarm posts with the fire station. The cost of placing those lines overhead would be £90, but if they were placed underground the cost would be £339.

Evidence was given on behalf of the Council, and Mr. A. Harrison, borough engineer, said the Council objected to all overhead wires in their district. He considered the erection of the proposed posts and wires would be objectionable and tend to deteriorate the district.

Mr. Hopkins reserved his decision.

German Consular Service.—It is announced that the appointment of commercial experts to various important German Consulates having been found so advantageous in promoting German exports, it is now proposed to extend the principle by supplementing them with special experts for answering technical questions. Their field of activity will lie in following the progress of the industrial development of a foreign country and reporting about all technical and engineering novelties. At the outset, these new experts will be appointed to the German Consulates at London, Washington, Paris, St. Petersburg, Vienna, Constantinople and Tokio. Technical members, as salaried officials, will also be appointed to the Consulates at Christiania, Budapest, Bucharest, Sofia, Alexandria, Athens, Rome, Moscow, Manchester, New York, St. Louis and Peking.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

*NOTE.—The undermentioned Applications (except those marked †) are not open to public inspection until after acceptance of Complete Specifications. COMMERCIAL AND INDUSTRIAL SECTION.

MUNICIPAL, FOREIGN & GENERAL NOTES.

BRITISH NOTES.

Alleged Theft of Electric Lamps.—At the Mansion House (London) Police Court on Tuesday, Jas. Wm. Waite, counterman, was charged on remand before Ald. Sir John Knill with stealing, and Thomas Powell, electrician, with receiving, 12 Tantalum lamps, value £1. 8s. 10d. Both were also charged with conspiracy to defraud Messrs. Siemens Bros. Dynamo Works (Ltd.), of 39, Upper Thames-street, E.C.

Mr. R. D. MUIR, who prosecuted, said Waite was in the employment of prosecutors as counterman in the electric lamp department, and Powell was a customer, but his legitimate transactions with the firm only amounted to a few pounds. In February last a serious shortage of lamps was discovered in the department, and that had increased by August. It was found on investigation that there had been a large exchange of old lamps for new with Powell, the number exchanged amounting to 37 per cent. of the total purchases. It was also found that lamps had been taken away by Powell, and that the transactions had not been entered in the books.

Evidence having been given, Sir JOHN KNILL expressed the opinion that a prima facie case had been made out, and he committed accused, who reserved their defence, for trial at the Central Criminal Court, admitting them to bail.

Battersea (London).—On Wednesday the Chairman of the Finance Committee reported to the Council that for the year ended March 31 last the electricity undertaking showed a net surplus of £3,118. The progress made during the past two years had been very satisfactory.

Bexley Heath.—As already announced the Council have adopted a revised scheme for carrying out wiring work on the deferred payment system.

Under the scheme forms of application and schedule for list of points proposed to be installed can be obtained from the electrical engineer (Mr. C. Mittelhausen), Car-sheds, Broadway, Bexley Heath. The installation is to be carried out by a contractor to the specification of the engineer. The Council's maximum contribution towards the cost of any installation is £1 per point installed, and no charge is made for supervision. If the cost of the installation exceeds the Council's maximum contribution, the difference between such contribution and the actual cost must be paid by the consumer (or the landlord) direct to the contractor. The installation remains the property of the Council until paid for as provided. The consumer (landlord or mortgagee) may purchase outright the whole of the wiring and fittings at any time on payment of the outstanding balance of the Council's contribution, plus 5 per cent. interest. The consumer (landlord and mortgagees) agree to refund to the Council the latter's contribution towards cost of installation by equal quarterly instalments of principal and interest and also undertake not to disturb or remove, or consent to the disturbance or removal of the wires or fittings without permission of the Council in writing until the same are fully paid for. The Council require no deposit or a guarantee of any fixed consumption of energy, except to the extent of the minimum charges payable by all consumers. These are: For quarters ending December and March respectively, 6s. per quarter, and for quarters ending June and September respectively, 3s. per quarter. Energy for lighting will be supplied at current rates, subject to usual cash discounts, and no meter rents will be charged. But for power, heating or cooking, the usual meter rent will be charged. In the event of the wires and fittings being destroyed or damaged beyond repair by fire or other cause, the balance then remaining unpaid of the value shall immediately become payable by the consumer (landlord or mortgagee). The installation includes wiring, fittings and the first supply of lamps. Lamps required subsequently may be purchased of the Council's electric lighting department. The Council's maximum contribution of £1 per point is estimated to include fittings of a plain character, and if more elaborate fittings are selected the excess cost will be paid by the consumer.

Bradford.—On Monday a deputation from Bingley Council waited upon the Tramways Committee to urge upon them the desirability of extending the tramways to Bingley.

Brighton.—Last week the Corporation adopted a report from the Lighting Committee recommending the re-construction of a turbine at the Southwick station.

Coun. Campbell, in moving the adoption of the report, said the committee were thoroughly convinced that the conversion would mean a very substantial saving. They were satisfied by the figures submitted by the engineer (Mr. John Christie) that they would at least save £1,000 a year on the cost of coal. By the suggestion now made the most recent turbine and No. 5, when transformed, would alone be sufficient to carry the maximum load on the present demand. The original cost of the set was £12,000, and the repayment of the capital was spread over 40 years. The alterations will cost £6,500.

Brumby and Frodingham.—The contractors for the laying of electric supply cables in this district (the British Insulated & Helsby Cables) are proceeding with the work, and it is anticipated that a supply of electric current will be available at the end of next month.

Bury (Lancs.).—At the last meeting of the Electricity Committee it was reported that the demand for power was increasing, and since the last meeting they had received applications from seven consumers for 100 H.P.

The engineer and manager (Mr. S. J. Watson) reported that the first day on which the machinery at the Chamber Hall station was connected up with the mains to assist the Rochdale-road station was Aug. 25. On the following Monday a regular supply was commenced, and the plant had since been in regular operation from 8 a.m. to 6 p.m., Saturdays and Sundays excepted, supplying up to about 800 kw. per day.

Church Lighting.—At the last meeting of the Stoke Newington (London) Borough Council the chairman of the Electric Lighting Committee (Coun. Savery) stated that there was a remarkable increase in the demand for electric current for church lighting, as during the past three months four churches in the borough had adopted electric lighting.

St. Nicholas Parish Church, Newbury, is now lighted electrically There are 127 lamps in all, including 78 25 c.p. Osrams in the nave, and 32 16 c.p. lamps in the chancel. The wiring was executed by Messrs. H. J. Cash & Co. to the specification of Mr. Pooley.

Clonakilty (co. Cork).—The Urban Council are considering a scheme for the erection of electricity works, and it is probable that a local company will be formed for the purpose of carrying out the scheme.

Croydon.—A new feeder cable is to be laid to the Drummond-road sub-station, at a cost of £1,700.

Dee Hydro-Electric Works.—Chester Corporation were recently recommended to adopt a scheme for utilising the water power available on the river Dee in the generation of electrical energy.

The scheme was drawn up by the borough electrical engineer (Mr. S. E. Britton), but before proceeding with it the Corporation decided to refer it to Mr. A. C. Hurtzig. In a report recently prepared by Mr. Hurtzig it is stated that the proposal is feasible. The plans provide for the erection of a power station on the site of the old Dee mills, and Mr. Hurtzig states that, assuming the weir to remain at the present height, the proposed scheme could not affect the navigation as much as did the mills when they were at work. With reference to the effect of the scheme on the fishery interests, he saw no objection to the erection of a fish pass at the weir, and generally speaking he considered that the authorities in charge of the fishery interests could not but be satisfied with the proposals of the scheme. He estimated the total cost at £12,500, while the yearly cost of working it would be £1,326, and the probable income £4,257. He was satisfied that the proposals contained in the power scheme were sound, and that by their adoption a certain and valuable source of electrical energy might be acquired for a comparatively small expenditure.

At the Council meeting on Wednesday Mr. John Owens said the Lighting Committee had not considered the report in detail, and when that had been done it would come before the Council with their recommendations.

The Deputy-Mayor said the committee could not proceed with the scheme until next spring, owing to the water and the tides.

Dorking.—The Council have obtained an order from the Board of Trade to extend the electric supply mains to Pixham and Mickleham.

East Ham.—The Finance Committee have decided that future applications for supply of current to clubs can only be acceded to on a substantial deposit being paid, and subject to agreement for the monthly payment of accounts.

Epsom.—Last week the Council further considered the report of the electrical engineer, Mr. A. C. Gilling, recommending the installation of a Diesel oil-driven set but, after discussion, it was decided to engage an electrical engineer at a fee not to exceed £25 to prepare a report upon the proposal, the engineer to be nominated by the President of the Institution of Electrical Engineers.

Gloucester.—It was reported to the Council on Wednesday that the use of meters for checking the electric current used by tramcars had resulted in a saving of £114, although there was an increase of 3,500 in the car-miles run. The cost of the 32 meters used was £ 00.

Heckmondwike.—The Electricity Committee have appointed a sub-committee to consider and report upon the terms submitted by the Yorkshire Electric Power Co. for supply of electricity in bulk.

Industrial Disputes.—An interesting report on Strikes and Lock-Outs and on Conciliation and Arbitration Boards in the United Kingdom in 1910, with comparative statistics for 1901-9, has been issued by the Labour Department of the Board of Trade. In a

Digitized by Google

preface to the Report, which is supplied by Sir G. R. Askwith, K.C., it is stated that—

The year 1910 was marked by considerable industrial disturbance; the number of workpeople (515,165) involved in disputes commencing during the year was the highest since 1893, while the aggregate duration (9,894,831 working days) of all the disputes in progress during the year has been exceeded on only four occasions during the last 18 years. The high figures for 1910 were caused by disputes in the coal trade of Northumberland, Durham and South Wales, in the shipbuilding industry in the north of England and in Scotland, and in the cotton-spinning industry of Lancashire and Cheshire. These five disputes alone affected 265,100 workpeople, and caused a loss in working time of over 6,500,000 working days. The effect on other industries cannot be statistically measured, but must have been very considerable. Of all the workpeople directly affected by disputes in 1910, 39 per cent. were involved in disputes as to the employment of particular classes or persons, and 24 per cent. in disputes as to hours of labour, both percentages being exceptionally high. Questions of wages, which are usually the most frequent causes of disputes, involved only 20 per cent. of the workpeople directly affected by disputes in 1910. Compromises were arranged for about two-thirds of the total number of workpeople directly affected in all disputes. A few disputes still remain unsettled, and in the remainder about half the workpeople were successful and half unsuccessful.

As in other recent years, methods of conciliation and arbitration were extensively used in 1910 in the settlement and prevention of labour disputes. The number of workpeople directly involved in disputes settled by such means in 1910 was the highest recorded in the decennial period for which statistics are presented in the report, while the number of cases annually settled by permanent boards of conciliation showed a further increase in 1910.

The report contains much interesting matter relating to trades disputes, conciliation, arbitration, &c., and it gives clear testimony of the skill displayed by Sir G. R. Askwith and the officials of his department in the handling of labour disputes. During the year 1910, 59 such disputes were settled, involving 204,384 persons, against 63 disputes and 92,872 persons in 1909. It appears that, with the exception of the mining and quarrying industries, the metal, engineering and shipbuilding trades adopt conciliatory methods of settling disputes most frequently, and in 1901-10 63 disputes, directly involving 61,553 people, were settled.

Library Lighting.—The formal inauguration of the electric lighting installation at the Stoke Newington public library and accessory buildings took place in the presence of a numerous company on Thursday last week. The ceremony of switching on the current was performed by the Mayor (Coun. H. J. Beavis, J.P.). The installation was his worship's Coronation gift to the borough, and the entire cost, which Coun. Beavis has defrayed, is £210.

The Public Library Committee of the borough had had before them several times the question of the electric lighting of the library, but, having regard to the cost and to the fact that the library rate is a fixed amount, which cannot be exceeded, the matter was deferred from time to time. Aware of the desire of the committee and the difficulty in the way, the Mayor announced at the July meeting of the Council, that he would defray the whole cost of the installation, and, upon an estimate by the borough electrical engineer (Mr. S. Hann), promptly gave a cheque for £200 on account. Tenders were obtained and the work was executed by W. J. Fryer & Co., under Mr. Hann's superintendence. The scheme has allowed for the liberal treatment of the reading hall, lending and reference libraries and offices. There are 187 Osram lamps. In the library hall are five 400 c.p. lamps, besides footlights and wing lights for the stage, and there is a special plug for an electric lantern for lectures. The old gasoliers in the lending and reference libraries and reading hall have been retained and adapted for electric lighting, lamps of 32 c.p. and 50 c.p. having been fixed to the pendants. Current is taken from the Council's mains. To commemorate the occasion a mural tablet of statuary marble has been fixed at the entrance to the lending library recording the gift of the Mayor.

L.C.C. Tramways.—The Board of Trade have approved the proposals of the L.C.C. for the construction of the tramway from Poplar to Barking-road Bridge, on the conduit system, the track work being laid in such a manner as to enable a change-point to be fixed later should arrangements be made for through running between Poplar and Canning Town.

Mines Inspectorship.—The Home Secretary, with the advice of the Civil Service Commissioners, has revised the scheme of examination for inspectorships of mines. These appointments will now be filled after a competitive examination limited to candidates nominated by the Home Secretary.

Candidates must be between 23 and 35 years of age, must hold a first-class certificate under the Coal Mines Regulation Act and must have been employed for two years as manager or under manager of a coal mine or in some other responsible capacity requiring regular attendance underground in a coal mine. An examination to fill several vacancies will probably be held at the beginning of next year. Applications for examination must be sent in before Oct. 15, 1911. Forms of application from the Private Secretary, Home Office, London, S.W. The salaries are:—Divisional inspectorships £750, rising by annual increments of £50 to £1,000; senior £500, rising by annual increments of £20 to £700; junior £300, rising by annual increments of £15 to £450.

The following are the subjects of examination:—(i.) English 400 (maximum marks), (ii.) elementary mathematics 200, (iii.) elementary geology 200, (iv.) Coal mining 1,000, (v.) ore and stone mining 300, (vi.) electricity in mines 300, (vii.) law relating to mines and quarries 200, (viii.) oral examination 400, (ix.) chemistry 400, and (x.) physics 400. Candidates must qualify in each of the subjects numbered (i.), (iv.), (v.) and (vi.), and must also obtain such an aggregate of marks in all the subjects numbered (i.) to (viii.) taken together as to satisfy the Civil Service Commissioners. Subjects (ix.) and (x.) are optional, and only one of them may be offered. The fee for the examination is £6.

Municipal Tramways Association.—The tenth annual Conference of this Association is being held at Glasgow. The proceedings, which will extend over three days, were inaugurated on Tuesday evening, when a reunion of the members and their friends was held in the Grand Hotel. The guests, who numbered about 200, were received by the President of the Association (Mr. James Dalrymple) and Mrs. Dalrymple and by Bailie Russell (convener of the Glasgow Tramways Committee) and Mrs. Russell.

The formal opening of the conference took place in the City Chambers on Wednesday morning, when the delegates were received by Lord Provost Sir Archibald M'Innes Shaw and the convener and members of the Tramways Committee. After the presidential address of Mr. Dalrymple had been delivered, a Paper on "The Common Good of the City of Glasgow: its Origin, History and Present Position in Relation to the Tramways Undertaking," was read by Councillor W. Nelson, sub-convener of the Tramways Committee. Luncheon was served in the City Chambers at one o'clock, and in the afternoon Councillor J. H. Rodger, chairman of the Newcastle Corporation Tramways Committee, read a Paper on "Tramways Finances and Policy." In the evening the delegates were entertained at dinner in the City Chambers by the Lord Provost and the convener and members of the Tramways Committee.

A full report of the proceedings, together with abstracts of the Papers read, discussions thereon, &c., will appear in the next issue of THE ELECTRICIAN.

Popular Lectures on Electric Lighting.—Two special popular lectures will be given by Mr. F. H. Taylor, A.M.I.E.E., A.M.I.M.E., on "Recent Developments in Electric Lighting and other Applications of Electricity," on Oct. 4 and 6, commencing each evening at 8 p.m. Tickets from the secretary of the Willesden Polytechnic, Priory Park-road, Kilburn, N.W.

Portsmouth.—The appeal of the Electric Supply Committee against the assessment of the electricity works has been abandoned, as the parties have effected a compromise. The assessment now stands at £7,785, a reduction of £2,000.

Presentations.—Mr. C. W. Hill, late tramways manager at Bournemouth, has been presented by the staff with an illuminated address and leather writing case, and Mrs. Hill with two framed water colours.

On his marriage on Sept. 21, Mr. H. W. Angus, borough electrical engineer at Eccles, has been presented by the Chairman and members of the Electricity Committee with a silver coffee service, and by the Corporation officials with a silver salver.

Shoreditch (London).—At the meeting of the Council last week the scheme prepared by the borough electrical engineer (Mr. C. Newton Russell) for the extension of the incandescent electric lighting of the borough was adopted.

The Lighting Committee reported that, following on the completion of the street lamps south of Old-street from gas to incandescent electric lighting, they had had under consideration for some time the question of converting the lamps in streets north of Old-street from gas to electric incandescent lighting by means of metal filament lamps. The number of burners now illuminated by gas in the district referred to is 1,055. The capital cost of laying about 14 miles of cables, in 160 streets, of sufficient size to serve, not only for the street lamps, but to meet any reasonable demand likely to arise, was £8,385 (including excavation work and reinstating footways, &c.), and the cost would be charged to electricity works capital account, the money being raised by loan, for which sanction would be obtained from London County Council. The cost of converting the street lamps for electric lighting is estimated at £695. 5s. and would be borne by the electricity works revenue account, and the Committee are including a proportion of this sum in their revised estimates. The proposed charge to the general rate is 37s. per 50 c.p. lamp per annum, including lighting and maintenance of lamps, which compares with the present cost of 40s. 3d. per annum, or a saving (including reduction of charge on lamps south of Old-street) of about £230 per annum. It is proposed to lay mains in the ordinary side streets of sufficient capacity to supply power up to 25 H.P. or 350 50 c.p. lamps, and in the smaller streets, mains sufficient to provide for 6 H.P. or 84 50 c.p. lamps.

Skelmorlie (N.B.).—The Skelmorlie Electric Supply Co. are laying electric supply mains in this district, and current will be available by the end of October. For private lighting the initial charge will be 6d. per unit.

Stirling.—The charges for electric current for public and private lighting and power have been recently reduced.

Stoke Newington (London).—Last week the Council adopted a recommendation of the Electric Lighting Committee to give notice

Digitized by Google

to the North Metropolitan Electric Power Supply Co. to terminate Schedule I. of their agreement with the Council at March 31 next.

The committee had reported that the accounts of the electricity department showed that had Schedule II. of the agreement been in operation during the past year a profit would have been made of £223. 8s. 2d., after payment of all working and management expenses and loan charges; and that the total repayment of loans at March 31, last amounted to £3,610. 13s. 1d.

Coun. White said that unless notice were given the Council would practically be presenting the company with something like £1,000. It was said that the recommendation was hardly fair, but he did not think the company were in need of sympathy. They had already received from the Council sums exceeding £5,000, and they were receiving yearly increasing sums which would be paid at a rate which the company themselves had asked.

Wakefield.—The Council have retained Mr. Ashton Bremner to advise them with regard to their destructor undertaking.

West Ham.—The Electric Light and Tramways Committee report having settled the claim of the Roland Hill Permanent Building Society, by payment of £275 (including costs), for injury to certain houses of the society, alleged to have been caused by noise, &c., at the generating station at Canning Town.

West Hartlepool.—Further negotiations have taken place between the Corporation and the local tramway company in regard to the municipalisation of the tramways in West Hartlepool.

The company were asked to pay 5 per cent. per annum on the Corporation capital expenditure, to establish a sinking fund and to contribute £150 per route-mile per annum for maintenance, and they were also to pay a rental. The company, however, say that such an agreement would involve them in heavy annual loss, and they offer to sell to the Corporation the remainder of the tramways in the borough, or to lease same on more favourable terms than the Corporation propose to them. Alternately, they offer to accept a lease of 42 years of all running powers on terms previously submitted.

Wireless Telegraph Note.—It is stated that from the time the Cunarder "Olympic" was in collision with H.M.S. cruiser "Hawke" until the former's safe arrival at Southampton, the Marconi wireless installation on board the "Olympic" was at work forwarding and receiving messages to and from all parts of the world. 150 messages were despatched to the account of the "Olympic" passengers, the total number of messages being a record.

Electric Supply Cricket League.—The following particulars of the points scored during last season by the clubs affiliated to this League have been issued and show that the St. James' Electric C.C. are the winners of the cup this year:—

St. James' Electric C.C. 17 points, City of London Electric C.C. 16, Kensington and Knightsbridge Electric C.C. 15, St. Pancras Electricity C.C. 8, Chelsea Electric C.C. 4, and Central Electric C.C. nil. The hon. secretary and treasurer (Mr. A. W. Seabright), 19, Cadogan-gardens, S.W., will be pleased to furnish any electricity supply cricket club with information in connection with the League.

B.E.A.M.A. Inaugural Dinner.—We are asked to announce that the British Electrical & Allied Manufacturers' Association (Incorporated) will celebrate their re-organisation by a dinner at the Hotel Cecil on Oct. 12. Applications for tickets should be made (by letter) to Mr. Hawes at Olympia, or 36, Kingsway, W.C., and from the following:—

London: Berry, Skinner & Co., 78, Upper Thames-street; General Electric Co., 71, Queen Victoria-street; Nalder Bros. & Thompson, 34, Queen-street, Cheapside; THE ELECTRICIAN Offices, 1, 2 and 3, Salisbury-court, Fleet-street, E.C.

Birmingham: Chamberlain & Hookham, New Bartholomew-street; Electric & Ordnance Accessories Co., Cheston-road, Aston.

Bradford: Phœnix Dynamo Mfg. Co., Thornbury Works.

Edinburgh: Bruce Peebles & Co.

Gateshead-on-Tyne: Sunbeam Lamp Co., Park-road.

Glasgow: Mavor & Coulson, 47, Broad-street, Mile End.

Manchester and District: Electromotors (Ltd.), Openshaw; Ferranti Limited, Hollingwood; Lancashire Dynamo & Motor Co., Trafford Park.

COLONIAL AND FOREIGN NOTES.

Argentina.—The "Review of the River Plate" says Messrs. Vega and Martinez have applied to Congress for a concession for a steam or electric railway from Port San Borombon to La Plata.

Mr. P. L. Pereyra has applied to the Buenos Ayres Provincial Government for a concession for electricity supply works in La Plata.

The Government of the Province of Cordoba have again invited tenders at an upset price of $150,000 (paper) for the purchase of their new electric power house in the City of Cordoba.

Punta Alta (Puerto Militia) Municipality recently received an offer from Messrs. Parcus & Co. to erect electricity works.

Australasia.—The Royal Commission on Melbourne Traffic has reported in favour of the electrification of the suburban railways and tramways and their management by a Greater Melbourne Council. The capital cost of the scheme (which includes the purchase of the Melbourne cable tramways) will exceed £5,000,000.

Mr. R. H. Harper, city electrical engineer, has just returned to Melbourne, after his visit to Europe and America.

Weymouth Proprietary (Ltd.) have presented a 10 kw. three-phase electric generator to the Working Men's College, Melbourne.

The Victorian State Legislative Assembly have passed a resolution moved by Mr. Watt, acting Premier of Victoria, for the appointment of a wages Board for tramway employes. Mr. Watt said the number of companies in Victoria was eight, and the men employed 1,518, with average earnings of 46s. 4d. a week. The males over 21 years of age numbered 1,450, earning 47s. 6d., and under 21 years 68, averaging 21s. 8d. The hours worked varied from 48 to 57½. The board was asked for by the Trades Hall Council and by the National Anti-Sweating League of Victoria.

Marsfield (V.) Shire Council has appointed Mr. G. B. L'reolre consulting engineer to report on a scheme for lighting the town by electricity.

Preliminary steps are being taken by the Turgamah (V.) Shire Council to secure electric lighting for that town.

Siemens Bros. Dynamo Works are supplying 30 motors (from 4½ to 23 H.P.) for Lysaght Bros. & Co.'s wire works at Pyrmont (N.S.W.). Current will be taken from Sydney Corporation.

Sydney Electric Light committee have adopted the suggestion of the city electrical engineer that the Council be recommended to duplicate the two 4,000 kw. sets recently supplied by Dick, Kerr & Co., at £17,285.

The adjacent local authorities are considering the desirability of carrying out a joint scheme for the erection of an electric power station to utilise the water power of the Barron Falls (Queensland).

The local Council have asked Manly (N.S.W.) Electric Light Co. to consider the question of erecting a refuse destructor.

Messrs. Younger & Howitt recently informed Prahran (Victoria) Council of their intention to abandon their contract for the construction of the Dandenong-road electric tramway in consequence of the strike of their workmen. The contractors, who are thus losing between £1,200 and £1,300, have handed over their plant to the Tramway Trust, and have offered to help the latter in any way possible.

Canada.—Prince Albert has resolved to spend £140,000 to develop power from La Colle Falls on the Saskatchewan River. 421 votes were cast, and only four were against the proposition. The original plans by R. H. and P. H. Mitchell are being inspected by Cecil B. Smith, the Winnipeg Power Scheme expert, and on receipt of his report contracts will be placed.

Port Arthur is an interesting city from many standpoints. Within a radius of comparatively few miles there are many waterfalls, capable combined of producing 145,000 H.P. Iron ore exists in enormous quantities in the district.

Dominion Statistics.—The "Canada Year-Book" for 1910, which was recently issued by the Dominion Government, gives the following statistics in regard to telegraph, electric lighting and traction companies:—

There are seven telegraph companies doing business in Canada, the Great North Western Co. (with 11,134 miles of line), the Canadian Pacific Railway Co. (12,257 miles), the Western Union (2,639 miles), Temiskaming & Northern Ontario Railway (265 miles), Algoma Central Railway (130 miles), Grand Trunk Pacific Railway (1,699 miles), and the North American Telegraph Co. (605 miles), total 28,729 miles.

The electric railways total 1,049 miles. The capital expended in Canadian electric railways totals $102,000,000. The annual revenue is $17,000,000, and operating expenses are $10,000,000.

The number of electric light companies registered under the electrical Inspection Act during the year ending March 31, 1910, totalled 398.

Hayti.—A concession has been granted for the erection of hydro-electric works to supply electric power to the railway which runs from Port-au-Prince to Piéton-Town (5 miles), and to the Port-au-Prince tramways (11 miles).

Hindu Temple Lighting.—It is reported that electric lighting is to be introduced into the Kalis Temple. This decision is the result of a recent conference of Brahmin pundits and scientists, who considered that there was "nothing objectionable in electric wires."

Panama.—A concession has been granted for the erection and equipment of electricity works and the construction of tramways in the town of David.

Prague.—The Municipal Council propose to issue a new loan of 2,000,000 crowns, 1,580,000 of which are to be devoted to the purchase of land for the erection of municipal electricity works.

Russia.—The Minister of Ways and Communications is preparing plans for the electrification of the railways round St. Petersburg. It is proposed to obtain the necessary electrical energy (about 28,000 kw.) by utilising the water power of the river Volkhoff, and 7,000 kw. will be available for industrial purposes after the railway supply is satisfied.

South Africa.—Pretoria Council have decided to extend the electric tramways at a cost of about £48,000.

Tokyo.—The Government have sanctioned the application of the Municipal Council to take over the electric tramways, and efforts will be made to complete the unfinished lines speedily and to improve the rolling stock. It is proposed to abandon 13 or 14 miles of existing track, and to build five new lines. The work will be finished by the end of 1914. The municipal authorities propose to build 500 new cars.

Digitized by Google

ELECTRICITY SUPPLY AND TRAMWAY ACCOUNTS.

Bath.—The minutes of the Electric Lighting Committee, which were presented at the Council meeting last week, contained the accounts of the electricity department for the year ended March last.

The accounts show total capital expenditure £168,364 (increase £3,420), of which £54,710 has been repaid. Revenue was £20,435, working and general expenses were £10,718, gross profit was £9,709, the nett result being a debit balance of £1,196. 1,973,280 units were generated, 427,789 supplied to public lamps, 10,596 by contract and 1,118,747 to private consumers by meter. The total maximum supply demanded was 1,058 kw. There are 164 arc and 195 incandescent lamps for public lighting.

The Chairman, in his remarks, said that in the previous year there was a loss of over £1,400, so they were showing some improvement, and whereas last year the revenue from lighting decreased by £431, this had been entirely wiped out by the increase of current for power, the nett increased revenue for the year being £574. With regard to the effect of the use of metal filament lamps, they had now turned the corner. They had made a larger number of connections this year than in any previous year. When he first became chairman of the committee, the revenue per 8 c.p. lamp was 5s. per annum; now (with the metal filament lamps) it had fallen to 2s. 5½d., which showed that consumers were now gettting the light at considerably less than half the cost some years ago. They had lost £300 less than last year, and after the introduction of the Diesel oil engine set they hoped to wipe out the loss altogether. If they could go on making both ends meet until 1918, they then liquidated one of their largest loans and established themselves in the position of being able to make a substantial profit.

Blackpool.—The quarterly report of the tramways department last week showed an increase of 265,431 passengers carried over the corresponding period of 1910, and of 3¾d. per car-mile in the receipts. The total receipts were £12,237, increase £2,247.

Bournemouth.—The accounts of the tramways department for the year ended March show capital expenditure £432,711 (increase £9,912), in addition to £130,330 spent on the Poole tramways, which are leased by the Corporation.

Revenue was £89,695, working expenses were £57,536 and gross profit was £32,159. The nett result, after crediting bank interest, &c., and paying capital charges, was a deficit of £130. Passengers carried were 14,686,368, car miles run 1,782,706 and units used 2,856,821. Total revenue per car-mile was 12·07d., working expenses (including power), were 7·74d.

Leicester.—At the meeting of the Town Council on Tuesday Ald. Smith, in moving the adoption of the report, of the Tramways and Electricity Committees, referred to the accounts of the Aylestone electricity undertaking for the half-year ended June 30.

It was, he said, the first balance sheet in connection with the undertaking since the transfer from the gas department. The half-year's revenue was £14,654, against £13,396. The disposable balance was £276, against £635. There had been an increase in expenditure of £1,534, as certain special expenses had had to be met during the half-year. There was now a steady increase in the consumption of electricity.

TRADE NOTES AND NOTICES.

TENDERS INVITED.

GRIMSBY Corporation invite tenders for supply of paper-insulated lead-covered cables, house fuse and main service boxes. Specifications and forms of tender from the borough electrical engineer, Mr. W. A. Vignoles, M.I.E.E. Tenders must be in by first post Oct. 16. See an advertisement.

The Tramways and Electricity Committee of BELFAST Corporation invite tenders for the supply of 2,000 ampere switchboard apparatus, field regulating rheostat and change-over switch. Specification and form of contract from the city electrical engineer, Mr. T. W. Bloxam, East Bridge-street, Belfast. Tenders to the town clerk, Mr. R. Meyer, by 10 a.m. of Monday, Oct. 9. See also an advertisement.

Tenders are invited up to Nov. 8 for the supply of ironwork, measuring instruments and protectors, switchboards, switchboard parts and accessories, and up to Nov. 22 for the supply of cable to the Postmaster-General's Department in QUEENSLAND; and up to Nov. 15 for the supply of telephone cords and earpieces to the Postmaster-General's Department in SOUTH AUSTRALIA. Tender forms, &c., from the Commonwealth Offices, 72, Victoria-street, London, S.W. See also advertisements.

Tenders are invited up to Dec. 20 for the supply of one branching multiple magneto switchboard at Broken Hill to the Postmaster-General's Department in NEW SOUTH WALES. Tender forms and specification from the Commonwealth Offices, 72, Victoria-street, London, S.W. See an advertisement.

Tenders are invited up to Nov. 21 for supply of one automatic or semi-automatic switchboard and equipment to the Postmaster-General's Department in WESTERN AUSTRALIA. Tender forms and specifications may be obtained at the Commonwealth Offices, 72, Victoria-street, London, S.W. See an advertisement.

Tenders are invited by the City of MELBOURNE for the supply of 8,000 yds. three-inch fibre conduit, suitable for laying underground in concrete, and to be used for containing lead-covered cables. Specification, tender form and conditions of tender from the Agents for the City Council, Messrs. McIlwraith, McEacharn & Co. Pptv. (Ltd.), Billiter-square-buildings, London, E.C., to whom tenders by noon of Tuesday, Oct. 3. See also an advertisement.

LONDON County Council require tenders by 11 a.m. Oct. 24 for supply of hand-power overhead crane, h.t. and l.t. cables and switchgear, &c., rotary converters and static transformers, for sub-stations. Specifications, &c., from the Clerk.

HACKNEY (London) Borough Council require tenders by 7 p.m. Oct. 12, for supply of 100,000 pairs of white open type arc lamp carbons. Specification, &c., from the Town Clerk.

MANCHESTER Electricity Committee require tenders by noon Oct. 4, for supply and erection of a 4,000—4,500 kw. low-pressure exhaust type turbo-alternator. Specification from the Secretary.

HASTINGS Guardians require tenders by Oct. 18 for the electric lighting of the workhouse premises, Ore, Hastings. Specification from Mr. S. Bumstead, 11, Wellington-sq., Hastings.

MORECAMBE Council require tenders by 10 a.m. Oct. 10 for reconstruction of a portion of the Bare tramway route. Specification from Borough Surveyor.

PERTH (N.B.) Corporation want tenders by Oct. 14 for coal storage hoppers, conveyors, capstans, electric generating plant for stoking machinery and extension of coal elevator and hoist. Specifications &c., from the Gas Engineer.

CARLISLE Electricity Committee require tenders for water softening and purifying plant (4,000 gallons per hour) and a main to feeder switchboard. Tenders to City Electrical Engineer by Oct. 14.

Tenders are invited up to Oct. 18 for the supply of 20 coin-in-the-slot attachments to the Postmaster-General's Department in WESTERN AUSTRALIA; up to Oct. 25 for supply to the Postmaster-General's Department in SOUTH AUSTRALIA of cable and paper sleeves; and up to Nov. 1 for the supply of 5,000 porcelain (No. 8) insulators to the Postmaster-General's Department in SOUTH AUSTRALIA. Tender forms and specification from the Commonwealth Offices, 72, Victoria-street, London, S.W.

The Metropolitan Water and Sewerage Board, Albert-street, BRISBANE, Queensland, want tenders by noon Jan. 30 next for supply and erection of one, two or three complete units, each consisting of power generating plant and pump or pumps to lift not less than 6,000,000 gallons per day. Particulars from the Secretary, and forms from the Agent-General for Queensland.

DUNEDIN (N.Z.) Corporation require tenders by Nov. 1 for supply of (1) 500 B.H.P. vertical type gas engine or Diesel oil engine, suitable for rope driving an a.c. motor and d.c. generator; and (2) direct-coupled vertical type gas engine or Diesel oil engine and d.c. generator (800 kw. at 550 volts). Specification at 73, Basinghall-street, E.C.

TULCEA (Roumania) municipality require tenders by Nov. 19 for electric lighting of the town.

Tenders are invited by the Municipal Council of PELOTAS (Brazil) for a 40 years' concession for the supply of electricity for power and lighting and the establishment and working of electric tramways. Tenders to Senhor Luiz M. da S. Pennafiel, Intendencia Municipal, Pelotas, up to 1 p.m. Nov. 14. A deposit (about £300) is required with each tender, to be increased by the successful tenderer to 25,000 milreis (about £1,670). Further particulars (in Portuguese) can be seen by British contractors at 73, Basinghall-street, London, E.C.

Tenders will be received at the Town Hall, SYZRAN, Russia, on Oct. 14, for the construction of an electric tramway and the supply of electrical energy for lighting.

Tenders are wanted by noon Nov. 22 for supply of motor generators, accumulators, main switchboard, cable, &c., to the South African Government Posts and Telegraphs Department, PRETORIA. Particulars from G.P.O., Johannesburg, or Cape Town.

Tenders will be received until Nov. 28 at the Directoria Geral Ministerio de Viaçao e Obras Publicas, Rio de Janiero, for harbour works at JARAGUÁ (Alagoas State) (estimated to cost £80,000), including the supply of six movable 1½-ton electric cranes, a fixed 30-ton crane and an electric lighting installation. Particulars can be seen at 73, Basinghall-street, E.C.

BONA (Algeria) Municipality require tenders for supply and erection of electric pumping plant to pump water from the Bou-Gos

Digitized by Google

water main to the Chateau d'Eau des Santons, nearly half a mile. The plant must lift 55 litres of water per second, and include a 440-volt c.c. motor. Prices must be submitted for two similar installations. Particulars from M. le Directeur du Service des Eaux, Hôtel de Ville, Bona, to whom tenders by Oct. 15.

TENDERS RECEIVED AND ACCEPTED.

East Ham Council have accepted the tender of the Ray Electric Co. for wiring the Manor Park Library, and that of Babcock & Wilcox for the installation of chain-grate stokers to two of the boilers at the generating station, at £325 per boiler. An order has been placed with W. Wood & Co. for two reels of figure eight trolley wire (about 2,700 lb.), at 7¾d. per lb.

Portsmouth Electric Light Committee have placed an order with W. T. Glover & Co. for cables at £331. 9s. 10d.

Sowerby Council have accepted the tender of the Northern Counties Electricity Supply Co. for supplying current to 74 lamps for 3 years at £105 per annum.

Cleethorpes Council have accepted the tender of the Western Electrical Co. for cables, and that of Ferranti (Ltd.) for meters.

Chelmsford Guardians have placed an order with F. H. Dennis for an electric fan at £14. 10s.

West Ham Council have accepted the tender of Willans & Robinson (at £11,384) for a 5,000 kw. turbo-alternator, and that of Babcock & Wilcox (at £9,790) for water-tube boilers.

Wood Green Council have entered into an agreement with the Chloride Electrical Storage Co. for the maintenance of the battery of accumulators at the baths for 12 years, at £16 per annum.

Southend Council have accepted the following tenders: Boydell & Co., nine feeder pillars, £114; John Spencer & Co., 53 traction poles, £241; Watlington & Co., 53 bracket arms and fittings, £195.

The Electric Light & Power Supply Corpn., Balmain (N.S.W.), have accepted the tender of Willans & Robinson (represented by Mr. T. K. Steanes) for a mixed-pressure turbine and G.E.C. 1,000 kw. generator.

The North British Rubber Co. have recently secured a further order for ebonite for the Admiralty.

Cleethorpes Council have placed an order with the Western Electric Co. for the supply and laying of vulcanised bitumen distributor and feeder cables, at £3,391, and with Ferranti Limited for meters, at £130.

Commonwealth Contracts.—The Postmaster-General's Department in New South Wales has accepted the tenders of R. Johnson, Clapham & Morris for 87 tons g.i. wire, at £11. 5s. per ton, and Thornton & Watson for wooden spindles, at 11s. per 100.

The Postmaster-General's Department in *Queensland* have accepted the tenders of W. T. Henley's Telegraph Works Co. for 1,760 yds. cable, at £112, 3,630 yds. at £172, 3,630 yds. at £224, 7,920 yds. at £276, and 1,540 yds. at £390 per mile; and the Western Electric Co. for 5,280 yds. cable at £462 per mile, 220 yds. at £525, 3,600 yds. at £634, and 1,800 yds. at £795 per mile.

BUSINESS NOTICES.

Mr. C. H. F. Muller, maker of X-Ray tubes, &c., is removing to 67, Red Lion-street, High Holborn, W.C. Telegraphic address "Florenzius London."

Mr. Wm. Scott Taggart, M.I.Mech.E., has taken an office at 22, Bridge-street, Manchester, where he will practice as a consulting engineer in general engineering and textile work.

The telephone No. of Mr. A. A. Campbell Swinton is now "Victoria 1506."

Wm. H. Gatley and J. Morehouse, electrical engineers and contractors, Water-street, Todmorden, have dissolved partnership. Debts by Mr. Gatley.

Manufacturers and Wiring Work.—Messrs. Johnson & Phillips announce that, owing to representations which have been made to them by some of their contractor friends, they have decided not to tender or accept orders for ordinary wiring work. Should any work of this nature be included in any orders they may receive for complete plant and cable installations, they propose, where possible, to sub-let and distribute the work among their contractor customers.

Plant for Sale.—Tenders are invited for the purchase and removal from the G.P.O., London, E.C., of some electric power plant which is being disposed of in consequence of the centralisation of the P.O. electric power supply. Specifications and forms of tender from the Controller of Stores, 17-19, Bedford-street, W.C. Tenders will be received up till 10 a.m. Oct. 31. See also an advertisement.

Mr. F. Lake, 132, Upper Thames-street, London, E.C., advertises for sale electrical sundries, cables, lamps, instruments, &c.

Agency.—A German firm of accumulator manufacturers advertises for a London firm with a connection among motor-car makers, &c., to take over the sole agency of their portable accumulators.

Business for Sale.—The business of an electric motor manufacturing company is advertised for sale in another column.

Patent Development.—The proprietor of patent No. 2,181/1905 for "Improvements relating to electric measuring instruments," desires to make arrangements for exploiting same in this country Applications to Messrs. Haseltine, Lake & Co., patent agents, 7 and 8, Southampton Buildings, Chancery-lane, London, W.C.

BANKRUPTCIES, LIQUIDATIONS, &c.

Wm. F. Flint, electrical engineer, 53, Jameson-street, Hull, has been adjudicated bankrupt. First meeting of creditors Oct. 5 at the O.R.'s, York City Bank Chambers, Lowgate, Hull, and public examination on Nov. 13 at the Court House, Hull.

A meeting of creditors of the Reno Electric Stairways & Conveyors (Ltd.) (in vol. liq.) will be held at the offices of T. F. Thorne, Lancaster, Farey & Co., 1, Basinghall-street, London, E.C., on Oct. 9.

Claims against the Howe Electrical Engineering Co. (Ltd.) to Mr. A. Thraves, 7, Victoria-street, Liverpool, by Oct. 11.

COMPANIES' MEETINGS AND REPORTS.

CLEVELAND & DURHAM ELECTRIC POWER (LTD.)—At the meeting on Tuesday Mr. Jas. Falconer, M.P., said the result of the past year's working was a gross profit of £20,973, compared with £12,942 in 1909-10. Contracts had been made with consumers this year amounting to 4,177 H.P. At the beginning of the year they had contracts amounting to 36,283 H.P., but now they amounted to 40,460 H.P. In addition, although the works to be supplied had not been completed, they had secured further contract for 12,500 H.P. Those figures showed a steady and satisfactory progress of the business, but they had been hindered considerably through the trade disputes of the past year. A satisfactory feature of the year's working was the fact that they had been able to secure arrangements for operating four additional waste heat stations, thus increasing the supply of electricity and affecting economies.

DICK, KERR & CO. (LTD.)—At the meeting of this company yesterday (Thursday), the chairman (Mr. John Kerr) in moving the adoption of the report and accounts (abstracted in our last issue), said that keen competition for orders had continued in all departments. The development of electric power in ironworks and the textile trades and in many other industries showed some progress. If this country did once lag behind Germany and America in the adoption of electricity it might fairly now be said that the greatest interest had been awakened. A considerable amount of plant had been ordered and quite a number of important installations were under consideration. At the company's Preston Works the highest grade of machinery could be turned out in an economical manner, by reason of good labour and the best modern equipment. Competition for business was acute enough between the home manufacturers, but it was increased by their market being an open one to Continental and American works. To any one who knew anything of manufacturing, the question of cost was largely one of output. To the working man, steady employment was better than intermittent work, even if the nominal wages were slightly higher per week. Work and plenty of it was equally essential to employer and employé. The directors were pleased to state that their efforts in the direction of the manufacture of steam turbines were meeting with satisfactory results. There could be no question but that development was on the right lines. In view of the enormous demand for metal filament lamps and the fact that the bulk of the lamps used of that class were of foreign manufacture, the directors, after careful investigation, decided to add a lamp factory. To avoid the danger of experimental work they had availed themselves of the experience of a Continental company. Their factory was now rapidly approaching completion and would very soon be in a position to turn out lamps second to none in the market. The prospects for the coming year were encouraging. As soon as international difficulties were settled, an amount of foreign work that was held in suspense would be proceeded with. Although they had been practically free from labour difficulties, there could be no doubt that strikes and threatened strikes all militated against business, by delaying work or causing postponement of orders. It was to be hoped that the Government would deal in no uncertain manner with "peaceful picketing," as the scenes that had recently taken place were a disgrace to the country and a source of public danger. Means could surely be found to deal with that clamant evil without inflicting any injury to the just rights of trade unions. The balance-sheet represented a rather uneventful year, although he was glad to say the result showed an improvement on the two previous years. The increase of £32,753 on capital expenditure was represented by the expenditure on the turbine business, the lamp factory and some additional plant at the Kilmarnock works. Debenture stock had been redeemed to the extent of £9,000. Since the issue of the debenture stock £46,570 has been paid off and a reserve fund of £150,000 created. It had always been the policy of the directors to strengthen the position of the debenture and preference shareholders. The contingent liability as co-obligants with the Edinburgh & District Tramways Co. in their liability to Edinburgh Corporation, under the lease of the tramways, would continue for about nine years. There need be no anxiety under that head, as the tramways were a remunerative undertaking of a first-class character. The company had

Digitized by Google

experienced, like other concerns, the greatest depreciation in the securities recognised as gilt-edged, but that had been allowed for in adjusting the total valuation. The re-arrangement of the staff necessitated by the lamentable death of Mr. Geo. Flett last year had been carried out and Mr. Schultz had been appointed assistant managing director. There was a desire by the staff and directors to commemorate Mr. Flett's memory in a suitable manner; the money subscribed by them, in conjunction with a handsome donation by his daughter and one hundred guineas by the Company, had been the means of endowing a bed in the London Hospital.

Mr. T. HACKING asked whether it was not desirable that the amount at which the goodwill stood should be shown in the balance-sheet.

The CHAIRMAN said the question of putting the goodwill item in the accounts would have the directors' consideration. He did not think, however, there was any company where the directors had taken more care to guard the company than they had.

The report and accounts were adopted and the dividends approved, and, after certain routine business, a vote of thanks to the chairman, directors and staff closed the proceedings.

LLANELLY & DISTRICT ELECTRIC LIGHTING & TRACTION CO. (LTD.) At the meeting on Monday Mr. A. R. Holland referred to the improved prospects of the company, and attributed that to the skill and ability shown by the contractors and managers, Messrs. Balfour, Beatty & Co. The whole of the streets of Llanelly were lighted electrically. They had secured a large number of private consumers for both lighting and power, in addition to the supply of street lighting, and the directors thought it their duty to consider the extension of the present plant. The construction of the tramways was commenced in February last, and two-thirds of the system was carrying passengers by June 16, the remaining third being opened for traffic a few weeks later.

NEW COMPANIES, STATUTORY RETURNS, MORTGAGES & CHARGES, &c.

NEW COMPANIES.

H. DAKIN & CO. (LTD.) (117,703.)—Reg. Sept. 19, capital £10,000 in £1 shares, to take over the business of builders and contractors, electrical and gas engineers carried on as H. Dakin & Co. Private company. First directors, H. I. Dakin (chairman) and F. W. H. Dakin. Reg. office, 200, Upper Richmond-road, London, S.W.

GLAIS ELECTRICAL CO. (LTD.) (117,744.)—Reg. Sept. 21, capital £2,000 in £10 shares, to take over the electric light undertaking carried on by E. Lewis at Glais, Clydach, Glam. Private company. First directors, E. Lewis, E. Bevan and W. Bowen.

INDUSTRIAL PLANT CO. (LTD.) (117,763.)—Reg. Sept. 22, capital £40,000 in £1 shares, to carry on the business of manufacturers of machinery, apparatus, appliances, cables and all kinds of plant for use in connection with the generation and supply of electricity, &c. First directors, F. S. Newall and R. P. Sloan.

LEITNER ELECTRICAL CO. (LTD.) (117,708.)—Reg. Sept. 19, capital £27,500 in £1 shares, to acquire from H. Leitner a licence to work the patents relating to inventions for the automatic electrical lighting of trains, motor cars and boats, &c. Private company. First directors are Right Hon. Viscount Templetown, E. T. Sturdy and Capt. J. D. Walker. Reg. office, 7, Prince's-street, Westminster, S.W.

MUNICIPAL TRAMWAYS ASSOCIATION, INCORPORATED. (The word "Limited" is omitted from title by licence of Board of Trade). (117,780.)—Reg. with 300 members, each liable for £1 in the event of winding up, to promote, encourage and facilitate the construction, extension, working and interests of tramways, light railways, railless traction and motor omnibuses, and similar works and vehicles owned and worked by municipal corporations or other local authorities, and in particular of electric steam and other modes of mechanical traction, and with a view to bring together officials and others interested therein. The subscribers are:—J. Dalrymple, Glasgow; H. E. Blain, West Ham; C. J. Spencer, Bradford; A. L. C. Fell, L.C.C. tramways; J. Aldworth, Nottingham; H. Linsley, J.P., Salford; and A. R. Fearnley, Sheffield. The management is vested in a Council, the first members of which are:—J. Dalrymple, H. E. Blain, C. J. Spencer, A. L. C. Fell, J. Aldworth, H. Linsley, J.P., A. R. Fearnley, A. Baker, Birmingham; P. Fisher, Dundee; S. Flint, Leicester; J. B. Hamilton, Leeds; J. M. McElroy, Manchester; H. Morley, Burnley; W. F. Russell, Glasgow; L. W. Slattery, Traffic manager, L.C.C. tramways; and E. R. Pickmere, Town Clerk, Liverpool.

STATUTORY RETURNS.

CHESHAM ELECTRIC LIGHT & POWER CO. (LTD.)—Return to July 14 gives capital £25,000 in £1 shares. 15,007 shares taken up. £1 per share called up on 7. £7 paid, and £15,000 considered as paid on 15,000 shares. Mortgages and charges, £8,200.

CHILI TELEPHONE CO. (LTD.)—In return to Aug. 3 capital is £360,000 in £5 shares. 66,000 shares taken up. £5 per share called up on 44,000. £220,000 paid. £110,000 considered as paid on 22,000 shares. Mortgages and charges, nil.

CROMPTON & CO. (LTD.)—According to return to Aug. 14 capital is £300,000 in £3 shares. 85,000 shares taken up. £3 per share called up on 83,600. £249,000 paid. £6,000 considered as paid on 2,000 shares. Mortgages and charges, £175,000.

ECUADOR TELEPHONE CO. (LTD.)—According to return to Aug. 3 capital is £100,000 in £5 shares. 5,000 shares taken up. £25,000 paid. Mortgages and charges, nil.

ELECTRIC & GENERAL INVESTMENT CO. (LTD.)—In return to Aug. 10 capital is £200,000 in £5 shares (20,000 ordinary, 100 founders' and 19,900 preference). All shares taken up. £1 per share called up and paid on ordinary and £5 per share on the founders' and preference. Mortgages and charges at date of return, £10,000, since issued £22,500. Capital increased to £201,500 by the creation of 30,000 deferred shares of 1s. each, on Aug. 18, 1911. Return of allotments made up to Aug. 18 shows whole of deferred shares allotted for cash.

ELECTRIC CONSTRUCTION CO. (LTD.)—Return to Aug. 3 gives capital as £400,000 in £2 shares (50,000 preference). 112,100 ordinary and 31,390 preference shares taken up. £2 per share called up on 2,100 ordinary and 18,245 preference. £40,690 paid. £246,290 considered as paid on 110,000 ordinary and 13,145 preference. Mortgages and charges, £182,700.

MORTGAGES AND CHARGES.

PRICES OF METALS (London).—*Copper*, cash, 54⅞; three months, 55⅜. *Lead*, English, 15⅛—15⅜; Foreign, 14⅞—15. *Spelter*, 27¼—27⅜. *Tin*, English, 182—183; Foreign, cash, 176; three months, 173. *Iron*, Cleveland, cash, 46/4½, three months, 47/2½.

COMPAGNIE GENERALE AUXILAIRE D'ENTERPRISES ELECTRIQUES.—This Russo-Belgian company shows for the past year a gross profit of 2,571,519 fr. A dividend of 25 fr. per share will be paid on the preference and 3½ fr. on the ordinary shares.

COUNTY OF DURHAM ELECTRICAL POWER DISTRIBUTION CO. (LTD.)—A circular has been issued to the shareholders stating that, while the profits for the first six months of the current year, as shown by the revised sheets, are slightly better than those for the same period last of year, the directors, in view of the disturbed position of the labour world and the possible dislocation of local trades which may follow therefrom, do not think it advisable that an interim dividend on the preference shares should be paid.

DIRECT SPANISH TELEGRAPH CO. (LTD.)—The directors have decided to pay, in addition to the dividend at the rate of 10 per cent. per annum on the preference shares, an interim dividend at the rate of 4 per cent. per annum (tax free) on the ordinary shares, both for the half-year ended 30th June, payable 2nd prox.

EASTERN TELEGRAPH CO. (LTD.)—The company announce the payment on Oct. 16 next of dividend at the rate of 3½ per cent. per annum (less tax) on the preference stock for the quarter ending Sept. 30, and the second quarterly interim dividend of 1¼ per cent. on the ordinary stock (tax free) in respect of profits for the year ending Dec. 31, 1911. The transfer books of the ordinary stock will be closed from Oct. 7 to 14, both days inclusive.

The company also announce the payment by warrants on Nov. 1 of interest for the half year ending Oct. 31 on their 4 per cent. mortgage debenture stock. The transfer books of the debenture stock will be closed from the 27th to 31st prox. inclusive.

EASTERN EXTENSION, AUSTRALASIA & CHINA TELEGRAPH CO. (LTD.)—The directors have declared an interim dividend for the quarter ended June 30 last of 2s. 6d. per share (tax free), payable Oct. 14. The share register will be closed from 6th to 13th prox. inclusive.

EASTERN & SOUTH AFRICAN TELEGRAPH CO. (LTD.)—The company announce the payment by warrants on Nov. 1 of interest for the half year ending Oct. 31 on their 4 per cent. Mauritius subsidy debentures. The transfer books will be closed from Oct. 27 to 31 inclusive.

ELECTRIC SUPPLY CO. OF VICTORIA.—This company's tramway and lighting receipts for June were £5,903.

KALGOORLIE ELECTRIC POWER & LIGHTING CORPN. (LTD.)—The directors have declared a dividend on the preference shares at the rate of 6 per cent. per annum for the six months ending 30th inst.

MEXICO LIGHT & POWER CO. (LTD.)—The directors have declared a dividend for the six months ending 31st prox. of 1 per cent. on the ordinary shares.

MEXICO TRAMWAYS CO. (LTD.)—The directors have declared a dividend of 1¾ per cent. for the quarter ending 30th inst.

REUTER'S TELEGRAM CO. (LTD.)—The directors have declared an interim dividend of 4s. per share, being at the rate of 5 per cent. per annum (tax free) for the half-year ended June 30.

RIO DE JANEIRO TRAMWAY, LIGHT & POWER CO. (LTD.)—The earnings of this company in August were £236,270 (increase £33,071). Aggregate from Jan. 1., £1,726,760 (increase £277,922).

NOTES.

The Olympia Exhibition.

EXCEPTION has been taken by the International Trade Exhibitions (Ltd.), managers of the Electrical Exhibition at Olympia, to some remarks which appeared in THE ELECTRICIAN last week on the subject of the Exhibition generally and the methods adopted for making it popular in particular. We think the International Trade Exhibitions (Ltd.) are quite unnecessarily perturbed. In the remarks we felt it our duty to make we believe we were voicing the general view of exhibitors and visitors alike. Certainly our own opinion is that the first week of the Exhibition—that is to say, from Saturday, September 23rd, to Friday, September 29th, inclusive—was a most unsatisfactory slice out of the four weeks' display at Olympia. Our object in calling attention to this matter in our last issue was to awaken the management in general, and not merely the International Trade Exhibitions (Ltd.), to a sense of the necessity for waking things up, and Saturday, September 30th, seemed to show some result. Whether cause and effect are as we assume them to be or not is of little import. How any remarks of ours could have been taken to reflect upon the management in any improper way we are at an entire loss to understand. It is, we presume, the object of everyone concerned, either in the management of the Exhibition or as exhibitors, to make money, directly or indirectly.

WITH a view to attract the public we are told that the Executive Committee have spent more on advertising the present than was spent on the last Electrical Exhibition at Olympia, and that more editorial comment in the lay Press has been obtained; also that the smaller attendance is due to the fact that tickets have not been purchased and distributed so freely as on the previous occasion. Be this as it may, there is a strong feeling that something more must be done. In support of this statement we need only allude to the action of exhibitors, to which we referred last week, and from which the executive officials did not hold aloof. As to what line any further effort should take, this question can, of course, only be decided by those who know all the facts of the case.

Now, as to the popular side of the show, a further acquaintance with the Exhibition only confirms our views. The lay visitor, if he does come, does not know what to look for, and is liable to become uninterested for want of direction. Why should there not be free or 1d. daily leaflet programmes distributed at the door, giving times of demonstrations and saying briefly what there is to be seen of popular interest, and where it is? The purely technical exhibits, intended for the technical buyer, are excellent, and we believe that satisfactory financial results therefrom are being obtained. But that is not enough. At the present day it is much more important to educate the public to the advantages of electricity in the home, the shop, and the small workshop than to make it a little easier for the technical buyer to place an order. Every manufacturer already has his showroom, where he can probably give a better display for the technical man than at Olympia. The

Digitized by Google

education of the public, on the other hand, is a more difficult matter and the reward all round immensely higher. The lighting load is quite small compared with that which is possible from other domestic applications, and it must not be forgotten that this load for power, heating and cooking would be accompanied by an immense demand for domestic appliances.

It is because we think thus that we have ventured to express our views in THE ELECTRICIAN. Whatever reflections we have made are, of course, intended to stir the management (and by the management we mean everyone connected with the conduct of the Exhibition) to a wider activity. There is so much to see at Olympia that we regard it as the duty of the Press, both lay and technical, to call attention to any and every omission calculated to minimise its popularity. We take the opportunity to tender to the lay Press our sincere thanks for their efforts to bring the main features of the Electrical Exhibition to the notice of the public. We hope that the management of the Exhibition (we repeat that we include all concerned in its conduct) will even yet see the importance of a larger popular attendance, and make things more attractive and easy for the lay visitor than hitherto. Our only desire in criticising what has been done and left undone is that the Exhibition shall be a thorough success. If technical journals are to be precluded from expressing their views upon the management and conduct of such important events as great public exhibitions, in which the said journals are intimately concerned, it seems to us that the chief duty of the technical Press is in peril—namely, the right of fair and reasonable criticism of public events. Even exhibition managers must not be supersensitive, or their occupation may also be imperilled.

Finally, we suggest that the Tuesday 2s. 6d. admission be abandoned, that in its place 6d. per person be the entrance fee on, say, Monday and Thursday, and that the old charge for tickets (3d. each, with a graduated reduction on quantities) be resumed. If, in addition, the demonstrations and popular exhibits were strengthened up, and attention drawn to them, we are sure that the lay visitor would be gratified and the Exhibition would benefit. The cooking demonstration given last Tuesday by the Brompton & Kensington Electricity Supply Co. is an example of what is desirable from an educational point of view, and we hope that such demonstrations will become frequent.

The Atlantic Cable Merger.

Full reports of the meetings of the proprietors of the Anglo-American and the Direct United States Companies will be found in this issue. The proceedings mark the most important phase of submarine cable finance since the formation of our great submarine telegraph undertakings in the early seventies, when an enterprise destined to become of immense importance to the world in general and to the British Empire in particular first took definite shape and comprehensive organisation. Events have moved rapidly since then, and we have witnessed many changes and many developments. These changes have not, however, very materially affected the Atlantic Companies, which have gone the even tenour of their successful way, due mainly to the arrangements which the far-sighted men who have presided over their destinies have engineered from time to time. There has been keen competition for traffic between the Companies having community of interests and the Companies outside the "pool," but this rivalry has, in the main, only resulted in increasing the volume of traffic, by which all parties concerned have benefited, especially the public. But times also have changed. The proceedings which we report elsewhere show that drastic modifications of the old working arrangements between the pooled Companies have become necessary, and these modifications have now been accepted by the members of the two British Companies chiefly concerned. The remarks of Mr. F. A. Bevan and Mr. E. M. Underdown will be read with varied feelings, and some regret may be felt that the operating control of the British cables is passing into American hands; this regret will, however, be tempered by the arrangements which have been made to safeguard the financial interests of the proprietors of these British cables, as well as by the fact that the Western Union Company have taken over the entire working staffs of the two Companies. The directors are to be congratulated upon the completion of their onerous labours, and we sincerely trust that the new position will operate to the advantage of the pioneers of the great enterprise of Atlantic telegraphy.

Small Supply Stations.

The County of Surrey will soon be noteworthy for the number of small Diesel engine power stations that are in operation within its borders. The most recent addition to these plants is that of the Egham & Staines Electricity Co., which, it is hoped, will be running in about two months' time. Although the undertaking is small, it possesses a few features of more than local interest. In the first place it is interesting to notice that the Board of Trade have for the first time—so far as we are aware—sanctioned the earthing of one pole of the supply on the consumer's premises. This admits, without employing a transformer with double winding, of the use of concentric wiring in which a metal sheath serves as the return conductor; and in view of the general desire to minimise the cost of wiring, it is an important step in this direction. One terminal at the consumer's end of the main fuse box is earthed to the case of the box, to which the armouring and lead of the service cable is also bonded; and a removable link allows the wiring to be disconnected when a continuity test is required. Again, the Board have approved of distributing mains run on the fronts of the houses, metal sheathed conductors being employed. By this method the cost of services is reduced and many extensions are possible which would otherwise be unremunerative.

Some supply undertakers are possibly not aware of the change in the law as to the erection of electricity supply stations made by the Electric Lighting Act, 1909. By clause 2 of that Act it is provided that it shall not be lawful for undertakers, except with the consent of the Board of Trade, to construct any generating station unless the construction is authorised and the land specified in a special

Digitized by Google

Act or Provisional Order, and it is also provided that the Board of Trade shall not give their consent until notice has been given to the local authority of the district in which the land is situate, and to owners and lessees of land within 300 yards of the proposed generating station. Usually, when there are objections by owners of property in the district a local inquiry is held by the Board of Trade into the circumstances of the case. This condition as to the erection of electricity works is an innovation introduced by the 1909 Electric Lighting Act, and, although it may be equitable to give residents in a district an opportunity of making reasonable objections to the erection of a power station, yet the clause may hamper the development of electricity supply in urban and rural districts. At all events, the necessity for holding an inquiry at Egham has resulted in considerable delay in the construction of the station. The objection to the station in the present instance may possibly have been due to lack of knowledge of the type of station proposed, as with a Diesel engine station a chimney and dust and dirt are absent. It might also be stated that at Egham the station is situated next door to the local gas works, so that no reasonable objection can, therefore, be made to it on the ground of the depreciation of local property or detraction from the amenities of the district.

Electrification of the Mont Cenis Tunnel.—The electrification of this tunnel, which has been worked by ordinary steam locomotives since its opening in 1861, is now in progress. The section which will be so worked reaches from Modane in France through the tunnel itself to Bardonnecchia on the Italian side, a total distance of about 15 miles. Single-phase current at a pressure of 3,500 volts and a frequency of 15 will be employed, and the overhead work on the open-air sections at each end is well forward. The supply will be obtained from the municipal generating station at Chiomonte where a power of 3,500 kw. at 50,000 volts and a frequency of 50 is available. A transformer station is being erected at Bardonnecchia. Owing to a variety of causes the proper ventilation of this tunnel has always been a matter of some difficulty, a state of affairs which should be made much easier by the proposed alteration.

"The Necessity of Safer, Quicker and Cheaper Railways, and Some Proposals Therefor."—In a Paper on this subject, read by Mr. C. R. Enock before the Society of Engineers, the author discussed the possibility of evolving an altogether new type of railway, and brought forward a scheme for light overhead railways on which single electric vehicles travelling at high speeds, with special provision against derailment by employing additional horizontal wheels, were to be used. If such a type were found practicable the present great cost of railway construction would be lessened, as land on the right of way would not be rendered useless for agricultural purposes, and embankments, cuttings, bridges, tunnels, drainage, ballast, sleepers, telegraph poles, and other similar equipment would no longer be necessary. He urged that national experiments for the solution of these problems should be carried out on a specially equipped site, in order to give greater scope to inventors and to evolve improvements, of d suggested that enquiry might be made into the possibility ana combination of railway and aeroplane.

Nature of Light Action in Selenium.—A recent issue of the "Physical Review" contains an article on this subject by Mr. F. C. Brown. The conclusions reached by the author are as follows: (1) Llight produces two changes of opposite sign in the conductivity of all selenium sensitive to light. (2) The amount of the change is a function of the time of illumination, as well as of the intensity and character of the illumination. (3) The selenium in the Giltay cell shows the same two changes under the action of high P.D.s that it does under the action of light. (4) The character of the conductivity curves for the four known varieties of light-sensitive selenium can be explained by assuming the existence of three components in dynamic equilibrium, under given illumination, temperature, pressure and electrical P.D.'s. (5) The effect of any agency that affects the conductivity of selenium is of the nature that it alters the rates of interchange between the components. (6) The experimental results can be explained to a first order of approximation on the assumption that of the three components which are in equilibrium according to the reaction $A \rightleftarrows B \rightleftarrows C$ only the B kind is conducting. (7) If we accept the view here proposed, the failure of Ohm's law becomes only an apparent and not a real failure.

Electric Traction in Sweden.—In dealing with this subject, the "Manchester Guardian" mentions that the State authorities hope to have the line between Gellivare-Kiruna-Riksgränsens, a distance of about 130 km. (80 miles), completed by 1914, and if the hopes of its success prove justified the general electrification of the entire State system will doubtless follow quickly. A special board to investigate the question as to the best method of exploiting the water-power and an electrical power bureau were recently appointed, and these bodies are now dealing with the economic and technical problems which would be involved in the electrification of the stretch between Gôteberg and Alingas, a distance of 46 km. (28 miles). A large generating station is to be erected near Elfkarleby, 145km. (90 miles) from Stockholm, and the State authorities are pushing the matter forward as much as possible. About 40,000 H.P. will be generated here. Over a thousand men are at present engaged on the Gellivare-Riksgränsens line, the generating station for which is being built near Porjus. This line is really part of the projected Inland Railway, which will run from Oestersund to Gellivare, a distance of 900 km. (550 miles). The southern portion (Oestersund to Ström) is also in actual construction, this stretch being 110 km. long (70 miles). The water-power already secured by the State represents, according to conservative estimates, 750,000 H.P.

"The Mechanical Properties of Hard Drawn Copper."—At the annual autumn meeting of the Institute of Metals recently held at Newcastle, Mr. D. R. Pye read a Paper on this subject in which he deplored the lack of any satisfactory definition of standard hard drawn copper. Although the Post Office specification was highly satisfactory for the sizes of wire used in telephone and telegraph construction, it was quite unsuitable for larger sizes. The various definitions adopted from time to time were reviewed, and it was suggested that the one at present adopted by the Engineering Standards Committee, viz., "the term hard drawn copper wire shall apply to copper wire which does not elongate more than 4 per cent. on a gauge length of 10 in. when broken by tension," though not contradictory of the properties of hard drawn copper, was unsatisfactory, since a specification should preferably fix a *minimum* elongation as a safeguard against the wire becoming brittle. An important point was that tensile strength per square in. and elongation at fracture both depended on the diameter of the wire. Experiments were described confirming a suggestion made by Mr. A. P. Trotter that this tensile strength per square in. diminished with increase in diameter according to a linear law. It was also shown that the elongation at fracture for similarly manufactured wires depended very much on the diameter, being considerably greater for larger sizes of wire. In view of these experiments it was suggested that a satisfactory definition of hard drawn copper wire would fix a minimum tensile strength per square inch given by the formula $T = 30 - 20D$, and a minimum elongation per cent. at fracture given by the formula

Digitized by Google

$e = 5D$, where D was the diameter in inches. This specification would hold good for all sizes up to 0·5 in. diameter. Finally, this suggested definition was compared with the specifications of the American Society for the Testing of Materials, and in an appendix was given the results of some recent experiments in America showing the effect of hard-drawing upon the electrical properties of copper.

Railway Electrification.—It is stated that the North Eastern Railway Company are considering the adoption of electric traction for their goods and mineral traffic on those sections of the track which are already electrified. In this connection we understand that Mr. V. L. Raven, chief mechanical engineer of the company, Mr. C. H. Merz, and other officials have recently left for the United States to investigate the question.

Electrically Worked "Stair Lift" on the Underground.—A new moving stairway, which connects the Earl's Court stations of the District Railway and Piccadilly tube, was opened to passengers yesterday. The vertical height which the staircase traverses is 40 ft., and the passengers first step on to a platform moving at 90 ft. per minute. This platform is level for some distance with a stationary platform alongside, but then it is formed into a series of steps, whose tread increases until a proper stairway is formed. This stairway moves upwards to the higher level, where the passenger steps off on to another stationary platform. Moving hand rails are provided at the side, and when the passenger arrives at the top there is no possibility of his remaining too long on the moving platform, for at a certain point a travelling belt on a level with his feet quietly and safely edges him off. In a similar way the journey can be made from the upper to the lower level, the trip in each case taking 160 seconds. Both "escalators" are driven by a motor through chain gearing. It is claimed for this arrangement that it has a greater traffic capacity than the ordinary lifts, owing to the elimination of waiting, and that it can deal with 10,800 passengers per hour, a number which would require five lifts working at full pressure.

Large Testing Outfit.—The "Electrical World" gives an account of a large portable testing outfit which has recently been put in commission by the Edison Electric Illuminating Co. of Boston. The apparatus consists of the following equipment: An 800 k.v.a. 2,200/30,000-volt transformer, an 850 k.v.a. 2,200-volt reactance and a 100 kw. four-bearing motor-generator set, consisting of a 100 kw., 1,200-2,200 volt generator, a 100 H.P. 1,200-2,300/4,000-volt motor, and a 125-volt exciter mounted on a wooden base and connected together by a flexible coupling, together with a starting compensator and two field rheostats. Other apparatus consists of two motor-driven blower sets, two 2,200-220 volt transformers, 12 lifting jacks, ammeters, voltmeters, portable current and potential transformers, and a frequency meter. The weight of this outfit is about 10 or 11 tons. As it is too heavy to go on one vehicle, it was decided to erect it on two 5-ton electric trucks, with battery equipment sufficient to make the run from a central point to any of the Company's stations at a reasonable speed in any sort of weather. The motor-generator set is installed on one of the cars and the rest of the apparatus on the other. Each truck will have a clear loading space 6 ft. wide, 15 ft. long and 6 ft. high. The weight without battery and load will be 7,500 lb., the weight of the battery, which is of the 60-cell Edison type, being about 2,400 lb. The rated speed of the car, on a hard, level, asphalt road, will be 7 miles per hour, and the estimated mileage on one charge on the same sort of road, is 30 miles. The outfit is intended to have sufficient capacity to test 5 miles of underground cable consisting of 34/0 conductors, lead-sheathed cable, built for 15,000 volts working pressure.

Electrically Operated Pumping Stations.—According to "Engineering News" four sewage pumping stations have been installed at Grand Rapids, Mich., to handle the entire sewage of that city during the times the Grand River, into which all the sewers empty, is in flood. The normal flow of the river is such that it can be forded at any place, but during flood periods, which generally occur in the spring, the river rises 15 to 20 ft. in a few hours. The small drop between Grand Rapids and the lake allows this water to back up and flow into the sewers, thus causing serious damage in the basements in the low section of the city. To prevent the constant recurrence of this damage the river has been dredged and enclosed between concrete walls 20 ft. in height. The water is prevented from entering the sewer outlets by special valves. During the normal flow periods the sewage is discharged into the river as before, but at flood periods the sewage is discharged into a sump pit, from which it is pumped over the wall by centrifugal pumps. Four pumping stations are required for the four sewer outlets. One station is equipped with two 18 in. centrifugal pumps operating under a normal head of 3·1 ft. with a capacity of 12,000 gals. per min., driven by 30 H.P. electric motors direct connected. Two stations are each equipped with two 24 in. and one 12 in. centrifugal pumps, with a capacity of 17,000 gals. per min., driven by 60 H.P. motors direct connected. The fourth station, which is at the terminus of the east side main sewer, has four 40 in. centrifugal pumps operating under a normal head of 6·7 ft. with a capacity of 47,000 gals. per min. These pumps are driven by 175 H.P. motors direct connected. Each station is also equipped with a priming pump belted to their driving motors. The power is supplied by the Grand Rapids Muskegon Power Co. No attendance is needed at the stations except during flood stages of the river, when an attendant goes to the station, closes the main line switch and also the valve on the sewer outlet. The sewage then flows through a by-pass into the sump pit. When the water reaches a fixed level the operator starts the pumps and runs them as long as is necessary.

Electric Traction in Vienna.—The report on the working of these tramways for the year 1910, as published in our Austrian contemporaries, shows that 271,584,931 passengers were carried, as compared with 267,449,171 passengers in the year 1909. This represents an increase of 1·5 per cent., as compared with 9·1 per cent. for the preceding year. The unfavourable result was due partly to an increase in fares and partly to poor weather. There were operated 49,822,147 car-miles, an increase of 5·84 per cent. The gross earnings were £1,713,066, an increase of 13·9 per cent. On the electrically operated lines of the system the operating expenses, exclusive of "welfare" work, constituted 60·9 per cent. of the gross earnings, as compared with 61·1 per cent. in 1909. The average earnings were 7·7d. per car-mile, an increase of 7·6 per cent. The average receipts per passenger were 1·61d., compared with 1·45d. in 1909. The total mileage of the system, measured as single track, was 312 miles. The 9,786 employés of the company received £693,198 in 1910, an increase of 14·5 per cent. over the year before. This sum was equivalent to 40 per cent. of the gross earnings. In addition 6 per cent. of the gross earnings was set aside for employés' welfare purposes, such as pensions and sick benefits. The use of car meters has produced a steady decline in the current consumption per car-mile. In one case the clocks showed a difference of 68 per cent. in the efficiency of two motormen who were operating under the same speed conditions over a given route. In another test it was found that a good motorman maintained the schedule for 312 days with 33,200 current-minutes, whereas a poor motorman required 55,070 current-minutes. Premiums for current saving were awarded to the amount of £2,305 for a total of 6,433 cases. The improvement of the motormen is shown by the fact that 28 per cent. received premiums in 1910 as compared with 15 per cent. in 1909. The car-meters on the cars are supplemented by clocks which have been installed at 48 time points. These clocks have been found very effective in spurring the motormen on to maintain their schedules and reducing energy consumption, and in aiding statistical work such as mileage determinations. At the end of the fiscal year there were 1,201 motor cars and 1,348 trailers in service. The latest rolling stock, numbering 99 motor cars and 205 trailers, is of the vestibule type with separate passages for entrance and exit, as in the American prepayment cars. These cars

Digitized by Google

have reduced the length of stops by some 25 per cent. The new motor cars use interpole motors which are large enough to haul two trailers. The running and braking resistance grids are placed under the seats for use as heaters.

urrent Topics.

Subjects of current interest dealt with in this issue include the following:—

Mr. J. Rezelman concludes his article on "The Determination of Synchronous and Asynchronous Reactance."

Mr. J. Härdén contributes an article entitled "Notes on Electric Furnaces."

We give an account of the proceedings at the annual conference of the Municipal Tramways Association last week. The Paper by Messrs. R. G. and J. G. Cunliffe on "Tramcar Meters" is referred to in our Leading Article, and a lengthy abstract will be found on another page of this issue.

A joint Committee of the Municipal Electrical Association and the Municipal Tramways Association has drawn up a report on "Charges for Electrical Energy Supplied for Traction Purposes from Combined Stations."

The foundation stone of a generating station to supply Egham and Staines was laid last Saturday by the Lord Mayor of London. This supply undertaking contains several features of interest.

We analyse the accounts for the year ended February 28, 1911, of the Melbourne Corporation electricity supply undertaking.

A further instalment is given of the Paper read by Mr. T. F. Wall before the British Association, entitled "The Single-phase Repulsion Motor."

We continue our account of the exhibits at the Olympia Electrical Exhibition.

A difference has arisen between Bermondsey Council and London County Council in regard to the granting of loans for electricity supply.

The deputation from Edinburgh Council who inspected the Leeds and Bradford rail-less traction system have now prepared their report on the subject.

Rotherham Council have received permission for a loan of about £2,000 for tramways.

Worthing Council have received sanction for a loan of £4,532 for extensions to station buildings and plant.

Barrow-in-Furness Corporation have decided to substitute electric for gas lighting in over 2 miles of thoroughfares, the number of electric lamps being 162.

PERSONAL NOTE.

Mr. F. W. Wilson is to hold the position of Government electrical inspector, Bombay, for a further term of four years, the extension of the period of service having been sanctioned by the Secretary of State.

APPOINTMENTS VACANT AND FILLED.

The Governing Body of the Northampton Polytechnic Institute, London, invite applications for a part-time appointment as day lecturer in mathematics in the engineering day courses. Salary £20 per session for eight hours' attendance per week. Further particulars, conditions with forms (which should be returned by 14th inst.) can be obtained from the principal, Dr. R. Mullineux Walmsley.

A meter inspector is required to repair, test and read slot and flat-rate meters, and to take charge of test room. See advertisement.

Mr. R. Lawson, formerly lecturer at Manchester Technical School, has been appointed instructor of telegraphy and telephony at the evening classes of East Ham Technical College.

Mr. A. Campbell, senior assistant superintendent, has been appointed by the Great Indian Peninsula Railway Co. as telegraph superintendent, in succession to the late Mr. J. E. Neale.

Mr. Fred Farrar has been appointed demonstrator and lecturer in electric wiring at Fleetwood technical school.

Mr. E. Meigh, M.Sc., has been appointed demonstrator in physics at the Battersea Polytechnic.

Mr. A. J. Maloney, A.R.C.Sc. (Dublin), has been appointed to the assistant lectureship in physics at St. Andrew's University.

INSTITUTIONS AND SOCIETIES.

International Congress of Applied Chemistry.—The eighth International Congress of Applied Chemistry will be held at Washington on September 4, 1912, and at New York from September 6 to 13, 1912. At the opening meeting the President of the United States, who is patron of the Congress, will welcome the delegates. The organising committee have already prepared notices calling on secretaries of Chambers of Commerce and of Educational Institutions in the United States to co-operate so as to give delegates opportunities of inspecting the commercial and educational facilities which are available in that country. Great interest is being taken in the affairs of the Congress by the United States Government, and it is therefore hoped that chemists all the world over will assist to make the gathering a success. All communications should be addressed to the secretary, Mr. B. C. Hesse, at 25, Broad-street, New York City.

Students' Section of the Institution of Electrical Engineers.—The honorary secretary desires to call the attention of such members of this section as wish to read Papers, to the fact that it is necessary for notice of their intention to be sent him *immediately* in order that an announcement may be embodied in the programme which is now being drawn up. Students intending to read Papers should therefore communicate with Mr. D. Betts, 3, Fordwych-road, London, N.W.

EDUCATIONAL NOTICES.

University of Durham.—Armstrong College, Newcastle-upon-Tyne.—Courses of instruction are provided in mechanical, marine, civil and electrical engineering, naval architecture, mining, metallurgy, agriculture, pure science, arts and letters. Particulars from the secretary, Mr. F. H. Pruen, M.A.

Scholarship Award.—In the competition for the entrance scholarship to the Faculty of Engineering at University College (of the value of 120 guineas) C. H. Avery (Southend Secondary School) and G. G. Dawson (Tollington School) were bracketed equal for the scholarship.

ARRANGEMENTS FOR THE WEEK.

SATURDAY, October 7th.

ASSOCIATION OF ENGINEERS-IN-CHARGE.

1:55 p.m. Leave Liverpool-street Station for Chelmsford. Visit to the Works of the Marconi Wireless Telegraph Co.

MONDAY, October 9th.

GRADUATES' ASSOCIATION OF THE INSTITUTION OF MECHANICAL ENGINEERS.

8 p.m. Meeting at Storey's Gate. Paper on "The Advantages of the Steam Turbine as compared with the Reciprocating Engine," by Mr. W. A. Hatch.

WEDNESDAY, October 11th.

ASSOCIATION OF ENGINEERS-IN-CHARGE.

8 p.m. Meeting at St. Bride's Institute, Bride-lane, Fleet-street, E.C. Presidential Address by Mr. W. H. Maw.

THURSDAY, October 12th.

BRITISH ELECTRICAL AND ALLIED MANUFACTURERS' ASSOCIATION.

2:30 p.m. Council Meeting at Olympia.

FRIDAY, October 13th.

JUNIOR INSTITUTION OF ENGINEERS.

6:30 p.m. Visit to the "Model Engineer" Small Power Engineering and Scientific Exhibition at the Royal Horticultural Hall, Vincent-square, Westminster.

THE LONDON ELECTRICAL ENGINEERS.

Officer Commanding, Col. H. M. Leaf.

The following orders have been issued:—

Drills for efficiency (1911-1912) will commence at Head-Quarters on Thursday, November 2, 1911, and Head-Quarters will be open as follows from that date: Daily (except Saturdays), 10 a.m. to 10 p.m.; Saturdays (unless otherwise ordered), 10 a.m. to 12 noon.

MELBOURNE ELECTRIC SUPPLY ACCOUNTS.

The Report of the Electric Supply Committee of the City of Melbourne shows that, for the year ended February 28, 1911, the Corporation electric supply undertaking made a profit of £19,532, after paying capital charges, &c., and setting aside £20,766 for depreciation and renewals. It should be noted, however, that the contribution to the sinking fund was only at the rate of 1 per cent. on the capital. As an offset to this low rate of repayment, we notice that the Committee recommended the setting aside of a further sum of £5,000 for depreciation and renewals, whilst the "Town Fund" only benefited to the extent of £9,500.

The diagrams attached to the Report indicate considerable activity in electrical matters in Melbourne. Thus, the number of units sold for private lighting increased by 149,028, in spite of the growing use of metal filament lamps. Whilst the power sales increased by no less than 537,969 units. The total output for all purposes was 8,920,489 units, as follows:—Private lighting 3,803,091 units, power and heating 3,098,960 units, street lighting 1,736,695 units, municipal buildings 281,743 units.

In connection with the private lighting load it is interesting to notice that the Electricity Department provide free lamp renewals to consumers using carbon lamps. The growing use of metal filament lamps, however, has led the Committee to consider how far consumers using these lamps can be given an equivalent benefit. The main difficulty arises in the case of consumers who have installed both types of lamps; but the Committee hope to evolve a satisfactory scheme.

The total number of consumers connected to the mains was, on February 28 last, 3,758, 1,530 of these taking a supply for power and heating. The number of consumers added during the year was 546, as against 359 in the previous year. A considerable proportion of the new connections were for power and heating, 175 motors, representing 887 H.P., having been added, bringing the total number of motors connected to 1,616, and the total horse-power to 5,571. Of these motors, 394 have been installed by metal and wood workers, 317 by clothing and boot manufacturers, 271 by printers, and 189 for elevators and hoists. The return of the Government statist shows that at the end of 1909 the power employed by factories was as follows:—

Steam.		Gas.		Electricity.
1,192	.....	797	.....	802

Six years previously (that is in 1903) the respective figures were—

1,316	.....	724	.....	195

It is interesting to notice the smaller use made of steam, the practically stationary position of gas engines, and the development of the electric drive.

During the past year the question of making provision for the anticipated load of the winter of 1912 has been under consideration in regard to an extension of the plant. The relative merits of a battery erected on a central site in the city and additional generating plant at the power station have been discussed, the Council finally deciding in favour of the installation of a battery. The cost of this battery is estimated at £21,000.

Further points of interest in the Report are that increasing attention is being given to canvassing, with very satisfactory results; and that in future the electric supply accounts of the Corporation are to be made up to December 31 instead of the end of February, so that they may be brought into line with the General Accounts of the Corporation.

From our analysis of the Accounts below; it will be seen that there is little change to record in the cost per unit sold. All surplus steam from the city refuse destructor was, as in previous years, used at the power station. The Council have during the year entered into a contract with the State Mines Department for a supply of slack coal at 10s. 7d. per ton, as against 16s. 10d. paid under a previous contract with a company. The relative calorific value of the new fuel is from 80 to 85 per cent. that of the old supply.

As to the revenue, this has increased by some £7,000; but in this connection it must be remembered that a reduction in the price per unit came into force in August of last year, and its full effect has not yet been experienced. The average price received for private lighting was 4·1d. per unit; and for power and heat 1·88d.

In the following analysis of the Accounts for the year ended February 28, 1911, the amount of each item per unit sold is set out, together with the figures for the previous year to facilitate comparison:—

		Per unit sold. 1910-11.	1909-10
Generating Costs.			
Coal	£14,741	0·43d.	0·43d.
Steam supplied by destructor	1,136		
Water and stores	901	0·02d.	0·02d.
Wages	6,898	0·19d.	0·21d.
Repairs and maintenance	3,350	0·09d.	0·12d.
Total Generating Cost	£27,026	0·73d.	0·78d.
Distribution Costs.			
Wages	£827	0·02d.	0·02d.
Repairs and maintenance	5,724	0·15d.	0·15d.
Total Distribution Costs	£6,551	0·17d.	0·17d.
Management, &c.			
Salaries	£5,812	0·16d.	0·17d.
Rent	1,240	0·03d.	0·04d.
Insurance	372	0·01d.	0·01d.
Advertising	88	0·00d.	0·00d.
Printing and stationery	403	0·01d.	0·01d.
Miscellaneous	1,009	0·03d.	0·02d.
Total Management Costs, &c.	£8,924	0·24d.	0·19d.
Special charges	£299	0·01d.	0·01d.
Public lamps (attention, &c.)	£7,468	0·20d.	0·21d.
Private lamps (attendance and renewals)			
Labour £3,149			
Material 3,012			
	6,161	0·17d.	0·19d.
TOTAL COSTS (*ex* Capital charges)	**£56,429**	**1·52d.**	**1·54d.**
Capital Charges.			
Interest	£17,533	0·47d.	0·50d.
Sinking fund	5,260	0·14d.	0·15d.
Provision for depreciation and renewals	20,765	0·56d.	0·58d.
Loans, flotation, &c.	844	0·02d.	0·03d.
Total Capital Charges	£44,402	1·19d.	1·25d.
TOTAL COSTS (*inc.* Capital Charges)	**£100,831**	**2·71d.**	**2·79d.**
Revenue			
Sale of current, lighting	£64,944		
Sale of current, power and heating	23,571		
Rent of meters	3,311		
Rent of arc lamps	921		
Miscellaneous	380		
Boundary lighting	475		
Public lighting, streets	21,665		
Public lighting, markets	3,040		
Public lighting, Town Hall	1,124		
Public lighting, other public places	932		
TOTAL REVENUE	**£120,363**	**3·23d.**	**3·33d.**
Balance	£19,532	0·52d.	0·54d.

A feature of the supply is the large output for street lighting, the revenue from this source being nearly equal to that from the power and heating sales; indeed, including the lighting of the markets and public buildings, the public lighting provides over 22 per cent. of the total revenue.

The capital expenditure during the year was £29,[illegible], bringing the total expenditure to February 28, 1911, to £605,023. £166,736 of this is on account of machinery, and £180,695 for mains.

Testing of Dirty Insulators.—The "Schweizerische Bauzeitung" states that the testing laboratory of the Swiss Electrotechnical Association has recently carried out a number of tests on porcelain insulators of different forms which had become blackened by locomotive smoke and soot after a considerable period of service. The insulation resistance showed a very appreciable reduction, but the breakdown voltage for a disruptive discharge was found to be reduced only 10 per cent. for dry insulators and 15 per cent. for those subjected to rainy conditions. As a result of these tests it is considered that particular precautions against soot are necessary.

TRAMCAR METERS.*

BY R. G. CUNLIFFE, M.SC.TECH., AND J. G. CUNLIFFE, M.SC.TECH.

Summary.—The authors show the importance of obtaining absolute values of the energy consumption of tramcars, and discuss the scope and behaviour under working conditions of watt-hour meters, ampere-hour meters and time-meters. The results of extensive investigations on the Manchester and other tramways are given, and finally the effect on the maximum demand of current, and the importance of brake setting and limitation of the motormen are considered.

It is now over 10 years since the first attempts were made to check and, in some degree, control the consumption of energy by the installation of meters on electric tramcars, and the failure, through structural weaknesses, of the early forms of watt-hour meter has, in the meantime, led to the widespread adoption of other types of meter which are not true energy meters, with the consequent desertion of readings of absolute, in favour of others of purely relative, accuracy. This relative measurement is, at the best, a compromise, and has given rise to considerable discussion.

Before deciding on the adoption of meters at Manchester, a careful study was made of the literature of the subject, and it was found to be impossible to determine, from this source, the type of meter likely to prove most useful. Experiments have accordingly been conducted with large numbers of each of the more important types of meter, and in this Paper comparisons are based upon the results of careful measurements carried out under actual working conditions.

True Functions of the Meters.—The result of a long series of investigations into the relationship between energy consumption and maintenance costs, carried out during the past few years at Manchester, has been to demonstrate clearly that in the case of certain

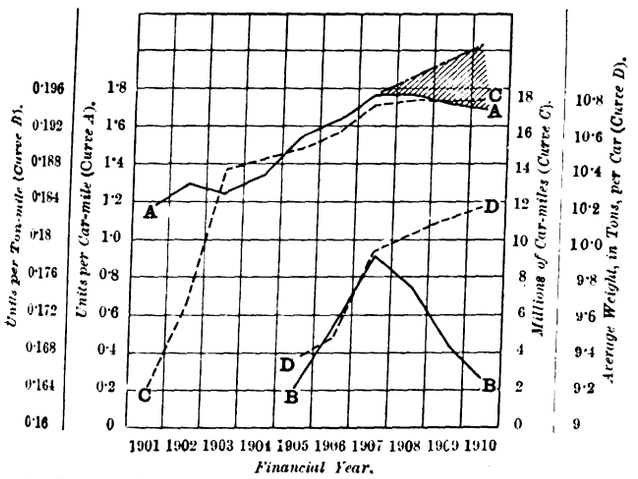

FIG. 1.—ENERGY CONSUMPTION STATISTICS (MANCHESTER CORPORATION TRAMWAYS).

Curve A. B.O.T. units per car-mile. Curve C. Car-mileage run.
" B. " " ton-mile. " D. Average weight per car.

wearing parts of the equipments, in which the energy losses increase with wear, the economical life is determined by the energy loss rather than by the extent of the wear. The methods employed at Manchester have been briefly referred to in the authors' Paper† presented at the Nottingham Conference of this Association. At that time the methods were still of too recent application to permit of results being given; but in the three years which have since elapsed savings have been made which have proved their efficacy and vindicated the somewhat increased maintenance costs.

Curves A and B, Fig. 1, show that the rate of energy consumption commenced to fall from the time that the methods were applied in 1908, the saving increasing as the equipments were gradually brought to a state of increased efficiency. The whole of the large increase in rate of energy consumption prior to 1907 was not due to the increasing inefficiency of the equipments, as the proportion of large bogie cars in use was steadily increasing whilst the covering of cars was proceeding at a rapid rate; but curve B shows that the units per ton-mile also increased to a considerable extent, and the effect of increasing weight ought to have been slightly to diminish this, since weight added to a car does not proportionately increase its rate of energy consumption, so that there was no doubt as to the importance of the increasing losses.

From curve C it is evident also that the mileage run was increasing rapidly, and the transmission losses, being roughly proportional to the square of the mileage, were becoming of relatively greater importance.

* Abstract of a Paper read at the Conference of the Municipal Tramways Association last week.

† *See* THE ELECTRICIAN, October 9, 1908, p. 1003.

The actual saving effected is shown approximately by the shaded area in curve A, and would have been greater but for the fact that the proportion of bogie cars has continued to increase, as also has the covering of existing cars, so that the average weight per car is much in excess of the 1907 value, as is shown by curve D.

It is difficult to obtain an exact knowledge of either the value of the saving effected or the cost of obtaining it, but although the first cost of renewing faulty field coils, worn gearing, &c., and adopting a heavier gauge of trolley wire where necessary, was comparatively heavy, it has already been balanced by the saving in energy, which, in addition, is cumulative over a number of years, during which the increase in manitenance charges will be very slight. The lost mileage due to defective equipments has fallen considerably from 1908 to 1910, and is still rapidly decreasing, thus indicating the state of increased efficiency of the equipments.

On the whole, therefore, by keeping down the losses it is possible to maintain the equipments in a better condition, with increased public safety and comfort, and, at the same time, to effect a saving, but this necessitates as exact a knowledge as possible of the values of the various losses, and one of the principal functions of the meters ought to be to supply this information. This, however, can only be done by meters capable of giving absolute values.

Another of the most important functions of the meters is to afford a means of measuring the comparative care and skill exercised by the motormen in the handling of their controllers. This can only be done, in the case of meters giving relative readings, on the assumption that every meter, working under similar general conditions, has the same percentage error; an assumption of the accuracy of which no proof has as yet been offered.

Types of Meter.—The watt-hour meter survived its early failure, and, by continued improvement, has been able, in many cases, to hold its own against its rivals, of which the only important ones are the ampere-hour meter and the time meter.

Electrical energy is a product of three components, viz., voltage, current and time, all of which, in traction work, are subject to simultaneous and rapid fluctuation over a wide range. The watt-hour meter measures all three components and is therefore theoretically complete. The ampere-hour meter measures current and time and assumes constant voltage; it is therefore partially complete; whilst the time-meter assumes both current and voltage constant and is therefore incomplete.

As an auxiliary meter the authors have developed a volt-hour meter,* the readings of which, when divided by the time, give the average value of the fluctuating voltage along a route, and in addition have used graphical recording instruments and measuring instruments of many kinds for checking purposes.

Accuracy of Meters.—Great pains have been taken in checking the accuracy of the meters by actual measurement from the following standpoints, viz. (1) As a means of measuring the energy component or components which each meter is specially designed to measure. (2) As true energy meters having regard to the simultaneous and rapid fluctuation of the three components. (3) As true energy meters when assisted by an auxiliary meter.

The authors have employed several forms of time-meter, and have found the most successful to consist of a clock having a small electric motor of peculiar design in place of the main spring, governing being obtained by means of a hair-spring and balance wheel, the motor providing the motive power and driving the clock when the current flows.

Experiments conducted with a contact maker rotating at a known constant speed, and completing the circuit for a predetermined part of each revolution, have shown the accuracy of the meter, at frequencies of operation corresponding to the quick handling of a controller, to be that inherent to clockwork generally, which, so far as meters are concerned, represents practical perfection.

Lord Kelvin checked his most delicate current-measuring instruments by means of the copper voltameter, and the authors have made use of the same method in order to check the actual error of the ampere-hour meter when in operation on the car. The apparatus itself is not susceptible to any of the peculiar conditions obtaining in traction work, vibration, if anything, assisting its action by causing circulation of the electrolyte. Care is required in the preparation and use of the cell, and, since this measurement forms the real basis of the Paper, the voltameter designed, and used with perfect success by the authors, is described in an appendix. It affords a means of measuring the ampere-hours to an accuracy of within half of 1 per cent.

Meters whose percentage error had been carefully determined in the test room were operated in series with the cell on service cars, and their error was found to be almost exactly as predetermined, showing that there was no appreciable error due to vibration and to the rapid

* Described on p. 971 of last week's issue of THE ELECTRICIAN.

Digitized by Google

fluctuation of the current. This is of great importance and proves the test-room calibration to be reliable.

Vibration reduces the friction, causing the meter to run slightly fast, but this is balanced by a slight retardation due to inertia effects. Both ampere-hour and watt-hour meters have the great advantage that they are not called upon to operate with currents lower than 30 per cent. of the normal full load for which they are designed, thus avoiding the inaccuracies frequently encountered in these meters at light loads, and enabling full advantage to be taken of the flat part of the calibration curve.

Ampere-hour meters of both mercury and commutator types, by various makers, have been tested and found to be capable of accurate operation within limits of 2½ per cent. over the whole of the working range, whilst, if accurate when installed, they have been found to be still accurate within 1 per cent. when tested after six months' continuous operation.

As the volt-hour meter is merely an ampere-hour meter designed for a very low current, and with a suitable series resistance in place of the shunt, its accuracy is that of the ampere-hour meter working at the most favourable parts of the load range.

Experiment shows that the average voltage on a route, as determined by the volt-hour meter, is practically independent of the car on which the volt-hour meter is installed, so that a single volt-hour meter will give the true average voltage for a route. Evidently, then :—

1. Every ampere-hour meter on the same route fails to register energy by the same definite percentage, and hence ampere-hour meters may be employed without correction for the purpose of placing drivers or cars in their correct order of merit as regards consumption of energy, although such readings could not be accurately used to determine the percentage difference between the values of the various men or cars.

2. The readings of the ampere-hour meters, when corrected for the true average voltage, give the actual energy consumption. This correction need only be applied to average daily, weekly, or monthly values for either each separate car or for the whole route, as desired, in order to estimate the value of the line losses by comparison with the station meters, or to compare the consumptions of cars on different routes.

There is no direct method of checking the accuracy under service conditions of the watt-hour meter, but numerous readings have been taken of watt-hour meters operating in series with ampere-hour meters, checked by volt-hour meters, both of known accuracy, and it has been found that watt-hour meters do not work very accurately on a line with wide voltage variation.

In Manchester, owing to high-tension transmission to a network of over 20 sub-stations, each having a number of short, heavy, low-tension feeders, radiating in all directions, the voltage regulation is within 10 per cent., especially as every section is fed from the centre, and unusually heavy trolley wires are used and parallelled for mutual assistance. On the Salford lines, however, owing to low-tension transmission over large distances, a voltage variation of some 30 per cent. or more was available for tests with the meters. On one route, of practically 22 miles per complete journey, the watt-hour meter appeared to read high at the lower voltages, the error, as compared with the corrected ampere-hour meter, exceeding 10 per cent. on a 35 per cent. voltage variation.

In order to check this error under more favourable conditions, the instrument was taken to the Polygon Testing Department of the Manchester Electricity Works, and tested by Mr. H. A. Ratcliff at various values of the current and voltage. The results, set out in a Table in the Paper, show that, at working values of the current, the range of error as measured in the test room may exceed 6 per cent. on a wide voltage variation, and, under the more severe practical conditions, the fluctuations of current and voltage being simultaneous and rapid, this range was exceeded. Evidently, if these results are typical of the watt-hour meter, it fails under the very conditions which would render its use desirable, and, whilst the above represent difficult conditions, they are, nevertheless, to be encountered on numerous tramways in this and other countries.

In the opinion of the authors it is better that one such widely fluctuating component alone should be measured by each meter, when there will be no mutual interference and the whole attention of the designer can be concentrated on the already sufficiently involved conditions.

If the time-meter is to be of any use as a means of obtaining absolute values, *i.e.*, as an energy meter, there must be a direct proportionality between its readings and the energy consumption, whilst, if it is even to be used as a means of comparison between drivers or cars, there must still be some definite relationship, although it need not necessarily be a direct one. In order to investigate this relationship whole routes have been equipped with both energy meters and time-meters, and the analysis of thousands of daily averages has proved that, for reasons discussed later, the time-meter cannot be made to give absolute values and, further, that it cannot be even employed with fairness to the men as a means of comparison between them, although the general tendency of a reduction in controller time is to cause saving of energy.

Diagrams given in the Paper show that there is no simple relationship between energy consumption and controller time ; in a typical case the drivers, second and third in order of merit as determined by energy consumption, were respectively 11th and 14th on the time-meter basis.

Influence of Meters on the Motorman.—Car meters are generally supposed to effect a saving in energy by promoting careful and skilful handling of the controller. They tend to prevent waste of energy by running with the brakes on, running on the resistance notches, approaching stopping places too rapidly, with consequent loss in braking, &c., and, whereas without meters the motorman might like to have his brakes so tight that he would only require to switch off the controller in order to stop his car, he will now complain if they are set too tightly and will watch jealously the state of the equipments of each car he may be called upon to drive, testing this by coasting down well-known inclines.

This increased care is what is really meant by the "moral effect" of meters, and in itself may result in fairly considerable economy, but skilful driving is a very different matter, and no amount of coercion, whether by meters or otherwise, can make a man drive skilfully if he does not know how to do so. The ordinary course of instruction teaches a man how to handle his car in a general way, and after some months of experience he becomes far more conversant with the equipments than is generally believed, but if the full measure of economy is to be effected, some supplementary training becomes necessary which will emphasize the effects of various methods of driving from the point of view of consumption of energy.

Results of Manchester Investigations.

Numerous experiments have been carried out in Manchester with a view to determining the effect of various methods of driving, and although the knowledge gained is by no means complete, many interesting results have been obtained.

It has been shown that there is no simple relationship between energy consumption and controller time, and various drivers can obtain the same value of units per car-mile with very different controller-minutes per car-mile. This is explained by the curves A, B and C in Fig. 2, which illustrate various relationships between the two quantities, These are curves actually given by three men on the Palatine route with exactly similar cars. The working range is from 2·6 to 4 controller-minutes per mile, as indicated, and it is evident that with the same value of the energy consumption these three men would have very different time-meter readings.

As is shown in Appendix II., there is an infinite number of curves varying in shape between these three, or having the same general shape but different heights, and a driver may work during part of a month along one curve and then change over to a totally different one. He may even drive in so haphazard a manner that his results plot out a large number of curves, suggesting, to a more superficial analysis, that there is no relationship at all. In the majority of cases, however, it is found that the man keeps to a certain general method of driving, giving points lying fairly close to a smooth curve which can be drawn and analysed. This is invariably the case when the man covers a wide range of controller-time per mile. It is men who maintain approximately the same value of controller-time from day to day whose results do not give any curve, and they are few in number.

Fig. 3 shows the theoretical relationship for each controller notch, and every man must work up and down all these curves and from one to another, remaining on particular curves for different proportions of the time according to his method of driving ; and when it is considered that each of the daily averages from which the actual curves in Fig. 2 are built up is compounded of a great number of such instantaneous values covering the whole range of Fig. 3, the complexity referred to is obvious, especially as each of these daily averages may fall anywhere within the rectangle of A, B, C, D, which represents their working range.

Further diagrams in the Paper show the great economy of parallel as compared with series operation and indicate the desirability of getting on to the running notches as quickly as possible consistently with the comfort of the passengers, which latter consideration can be trusted to restrain the drivers, owing to fear of complaints, from too quick starting.

The economy of parallel running is shown in the accompanying Table, which gives the average results of a series of observations taken on the Palatine route and is based on hundreds of journeys.

It is evident that series operation entails a comparatively long

PALATINE ROUTE.

Section.	Units per car-mile.	Controller min. per car-mile.	Units per controller min.	Av. speed (miles per hour).	Remarks.
All Saints' to Town, return.	2·26	5·28	0·429	5·39	Heavy City route. All series running, very frequent stops.
All Saints' to Birch Villa and back.	1·99	3·35	0·592	8·52	Urban route. Frequent stops. Mainly mixed series and parallel running.
Birch Villa to Terminus and back.	1·395	2·99	0·467	10·9	Suburban route. Good opportunity for parallel running.

of the controller, a comparatively low average time-rate of energy consumption as shown by the units per controller-minute, and a high distance-rate of consumption as shown by the units per car-mile.

Parallel running, on the other hand, necessitates a greatly reduced use of the controller, a slightly greater time-rate, and a much smaller distance-rate of consumption, and it is in this distance-rate, the units per car-mile, that economies are to be effected.

Returning to the curves in Fig. 2, it would appear that the use of the controller is mainly series in curve A, mixed in curve B, and parallel in curve C. The characteristic upward tendency is shown in curve C, which is evidently a much purer curve than the other two, where there is a greater proportion of mixed driving.

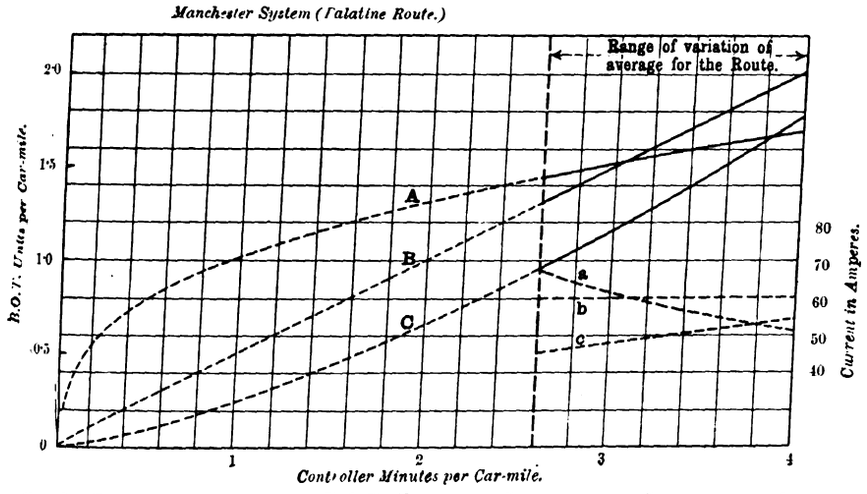

FIG. 2.—RELATIONSHIP BETWEEN B.O.T. UNITS PER CAR-MILE AND CONTROLLER MINUTES PER CAR-MILE. (Three typical cases obtained in practice.)

Maximum Demand.—If the installation of meters becomes general, e station engineer is threatened with a reduction of revenue in uch the same way, though not to the same extent, as that caused / the advent of the metal filament lamp, with the added disadvan-ge that the increased economy will not bring him an increase in the mber of his connections in the shape of cars, since the schedule opted is fixed by other than energy considerations. It is of interest consider the probable effect of this saving on the maximum de-nd, as there appears to be every probability of traction energy rges in the future being based upon a maximum demand rate.

The current taken by a car is shown in Appendix II., to be propor-nal to the average energy demand of the car in units per controller-nute; and current curves *a*, *b* and *c*, there obtained are shown by broken lines on Fig. 2. These correspond respectively to the ves A, B and C on the same figure, and their shape is accounted in the Appendix.

t is evident that as the controller-time diminishes, *i.e.*, as improve-nt continues, the average demand increases for a driver working ng curve A, remains constant for curve B, and diminishes for ve C. In the case of curve A, however, it will be observed that proportionate increase of average demand, as measured by current mall compared with the reduction in the time during which the nand continues, and hence, owing to the lesser probability of ny cars simultaneously requiring a supply of energy, the station ximum demand would be reduced even if every driver worked ng the curve A.

s a matter of fact, however, it is observed that any marked im-vement in driving is effected, not by working lower down a given ve, whether A, B or C, but by falling bodily on to a lower curve consuming less energy at very similar values of the controller-time, and this, if it became general, would proportionately reduce the maximum demand, being equivalent to a reduction in the value of the constant "a" (*see* Appendix II.).

Limitation of the Motorman.—The ideal method of driving, as regards energy consumption, would be to get fairly quickly into parallel, remaining there at full speed until approaching a stopping place, then to switch off at such a distance that the car would just come to rest without application of the brakes; but this long coasting would be wasteful of time and is prevented by the fixed schedule time, which is important in so far that it hinders the men in obtaining the best results and should be taken into consideration in comparing the records of men on different routes.

The Table given above shows the predominating influence of "Type of Route," the values given in the city part being much higher than for pure series running on account of the great number of stops, and the authors are of opinion that it is not possible to effect much saving on such routes, as there is practically only one way in which a man can drive, his whole attention being taken up in getting his car along at all.

Low-line pressure, due to bad feeding arrangements, compels the driver to remain longer on the controller in order to maintain a given schedule, but, as is evident from Appendix II., the average demand is reduced in practically the same proportion, so that the effect is to alter the relationship between energy consumption and controller-time without materially increasing the former. It is very difficult, therefore, to make a fair comparison between drivers or cars on different routes; and in a city like Manchester, where large numbers of part-day cars are run at the rush hours, separate comparisons must be made even between cars on the same routes.

Brakes.—One result of the installation of car meters is to call attention to the great importance of brake setting, and, however careful the supervision, cases of tight brakes are very common, causing great waste of energy. This difficulty is being met by the use of brake gear fitted with a conical drum, giving a large initial movement of slack chain and brake blocks with a leverage gradually increasing to a maximum when the block is on the wheel. This permits of an increased clearance between the blocks and the tyres.

Meter-Registering Dials.—In order to facilitate correct reading of the meters by unskilled men, the dials ought invariably to be of the cyclometer type with spring figures, and a tenths dial ought to be provided, the figures being painted red, whilst the other dials bear figures in black.

Clock-face dials invariably lead to confusion, and in the case of cyclometer dials without spring figures, it is possible to have two figures, each half exposed when a driver is being relieved, with the result that each driver, takes the figure most favourable to himself, and, as this generally occurs at the units dial, one unit is lost. If a tenths dial is provided, an error of reading in the last figure will be unimportant, whilst the other figures can always be corrected by a comparison of meter cards.

Results obtained from the use of Meters.—An analysis of the schedule recently compiled by Mr. Goodyer* shows that on 19 systems which have furnished complete replies the average saving amounts to £22·66 per meter per annum. The authors have had an opportunity of verifying the saving effected at Bury, and it may be accepted as a bona-fide example of the results to be obtained from the use of meters under the most favourable conditions. A reduction of 21·79 per cent. was made in the energy consumption corresponding to a saving of £41·6 per meter per annum.

This result, however, has only been obtained by the most unremitting attention on the part of Mr. Clough and his staff, supervision and time being devoted to the subject to an extent which would be impossible on much larger undertakings. It is quite out of the question to expect such results on a large city tramways; but, although comparatively little can be done in the driving, there is no reason why the full saving resulting from efficient equipments should not be realised, and so, in the case of such undertakings, the absolute values become proportionately of greater importance.

It is important to notice that the methods of employing the meters should be such as to exert a continual pressure on the men, as otherwise their improvement will not only gradually cease, but they will actually slip back into the old values. It has been found profitable in Manchester to fix a limiting value, slightly better than that ob-

* *See* THE ELECTRICIAN, July 7, 1911, p. 487.

Digitized by Google

tained by the best driver, for each route, and to encourage the men to aim at reaching that value.

Conclusions.—The authors are satisfied as a result of their numerous experiments that :—

1. The ampere-hour meter can, with proper supervision, be made to operate with an accuracy of within 1 per cent., and that its uncorrected values may be employed for the purpose of placing motormen and cars in their correct order of merit, whilst, when corrected for variation of average voltage by the volt-hour meter, its readings give the true energy consumption.

2. If percentage differences between the results of various men are required the corrected values must be used.

3. The watt-hour meter, owing to its greater complexity, more fraglie construction, susceptibility to lightning discharges, and greater inaccuracy, is not so desirable or valuable an instrument as is the corrected ampere-hour meter.

4. The time-meter, although very accurate in its measurement of time, cannot be trusted to measure energy within 10 per cent., and, if used at all, should only be employed, in conjunction with the energy meter, for purposes of investigation, in which connection it is very valuable.

5. The volt-hour meter is indispensable for many purposes, and ought to be employed on all tramway undertakings for the purpose of measuring average voltages.

6. On small undertakings, with light traffic, approximately equal savings may be effected in the driving and in the detection of faulty equipments, but, as the congestion increases, the state of the equipments becomes of increasing importance, more especially as regards the feeding and distributing system where the losses are a fraction of the total energy consumption, and do not merely affect the consumption of individual cars.

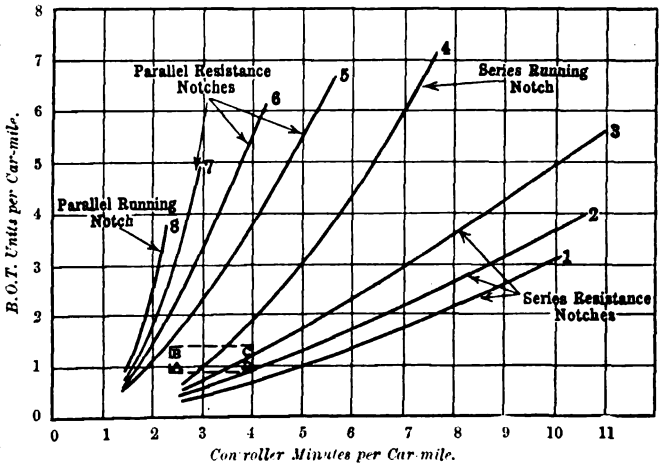

FIG. 3.—RELATIONSHIP BETWEEN UNITS PER CAR-MILE AND CONTROLLER MINUTES PER CAR-MILE FOR EACH CONTROLLER NOTCH OF A CAR EQUIPPED WITH TWO G.E. 52-27 H.P. MOTORS. (Monthly average for the Stockport route falls in the rectangle A B C D.)

In Appendix I. the authors describe a copper voltameter for use on tramcars. This was designed with special regard to the heavy rushes of current, liberal allowance being made in order to avoid loosening of the deposit. Temperature rise and facility for accurate weighing were also taken into consideration. In order to avoid a high temperature rise the voltameter was divided into four parts, each in a separate glass cell with air space on every side, the four cells being carefully parallelled by heavy copper strip in order to ensure equal division of the current. For accurate weighing a large number of plates were used, each weighing about 200 grammes. The plates were of soft drawn copper strip, and each of the four cells contained 6 anodes and 5 cathodes, each plate being 8 cms. wide by 20 cms. deep. A close, firmly adherent deposit was obtained of about 115 grammes weight per cell from each day's run, and a correction at the rate of $\frac{1}{200}$ mmg. per hour per square centimeter was made for solution of copper, from the plates in the electrolyte.

Appendix II. contains a discussion of the mathematical relationship between energy consumption and controller time. The theoretical curves, given in Fig. 3, show by their shape that the distance-rate of consumption of energy is an exponential function of the distance-rate of duration of controller time.

Thus, $U = a M^n$, where U = B.O.T. Units per car-mile, M = Controller-minutes per car-mile, and a and n are constants for any particular curve. This exponential form, with its inverse, the logarithmic function, is characteristic of the series electric motor, and its influence is evident from the shape of the practical curves, given in Fig. 2.

Differentiating this equation we get $\frac{dU}{dM} = naM^{n-1}$. From this it is evident that, with increasing values of the specific controller-time the curve will have an upward tendency if $n > 1$; a downward drop if $n < 1$; and will be a straight line of slope a if $n = 1$. This is illustrated in Fig. 2, where the actual equations to the curves are as follows, viz. :—Curve (A)—$U = 1{\cdot}02\ M^{0{\cdot}364}$; Curve (B)—$U = 0{\cdot}513M$; Curve (C).—$U = 0{\cdot}247\ M^{1{\cdot}422}$.

The influence of the value of the index n on the shape of the curve is of interest for several reasons. In the first place it accounts for the large number of possible working relationships since on the various controller notches widely different values of n are obtained, and the practical curves are composed of large numbers of these component values, which may be compounded in an infinite number of ways. In the second place the value of n is of interest from the point of view of station maximum demand. The value of the coefficient a determines the height of the curve.

Station maximum demand has been treated, in the text, from a consideration of the average energy demand per car; this during the time that current is flowing, being given by the ratio U/M; i.e., the energy units consumed per controller-minute.

From the first equation above, it is evident that $\frac{U}{M} = aM^{n-1}$, whence it appears that, with improvement, *i.e.*, with diminishing values of the controller-time per mile, the average demand per car will increase if $n < 1$, will remain constant if $n = 1$, and will fall if $n > 1$.

This is shown by the broken lines *a*, *b*, *c* in Fig. 2, these representing the variation in average demand, corresponding to the curves A, B, C, respectively. These curves, *a*, *b*, *c*, really represent the variation of the average current which has been employed as being more familiar than the ratio U/M, to which it may be shown to be directly proportional. Thus, $\frac{U}{M} = \frac{E.C.}{1{,}000 \times 60}$ kw. hours per controller-minute, or $C = k\ U/M$, whence $C \propto U/M$, where E = average line pressure in volts, C = average current in amperes, and k = constant for any given value of E. (120 at 500 volts).

The value of the average current is $C = kaM^{n-1}$.

THE DETERMINATION OF SYNCHRONOUS AND ASYNCHRONOUS REACTANCE.

BY J. REZELMAN.

(*Concluded from page 963.*)

Summary.—The action of the rotor of a synchronous alternator with respect to the stator is, in part, of a single phase and, in part, of a polyphase nature. The article deals with the reactance under various conditions of speed, &c., of the various possible combinations of single and polyphase stators and rotors; the polyphase stator with single phase rotor is in particular interesting. Machines with non-salient poles only are considered.

The above study will serve to explain various phenomena which will be met with in the following :—

Reactance of three-phase asynchronous motor, 175 *H.P.*, 8 *poles*, 3,000 *volts*, 50∼, 750 *revs. per min.*

The reactance of this motor has already been determined in the preceding article on "The Reactance of Asynchronous Motors."

1. *Stator three-phase, rotor three-phase.*—The leakage reactance per phase of the three-phase *stator* winding is :—

$$R_s = x_{ss} + x_{sk} + x_{sd} = 2{\cdot}72 + 0{\cdot}98 + 3{\cdot}1 = 6{\cdot}8w.$$

and of the *rotor* winding, reduced in terms of the stator :

$$R_r = 1{\cdot}5 + 0{\cdot}73 + 1{\cdot}6 = 3{\cdot}83w.$$

whence $$R_s + R_r = 10{\cdot}63w.$$

The fields due to the higher harmonics produce a reactance of *mean* value $0{\cdot}004R_o$. The main reactance per phase corresponding to the air-gap, $R\delta = 195w$. The current measured on light load is $I_o = 5{\cdot}22$ amperes for a voltage of 1,500 between phases, whence $R_o = \frac{867}{5{\cdot}2} = 167w$; hence there is a diminution $(195 + 6{\cdot}8^*) - 167 = 34{\cdot}8w$, corresponding to the reluctance of the stator and rotor iron.

* For the reactance of the stator alone it is, in reality, necessary to take $R_s + 0{\cdot}002R_o$, but this correction is negligible for the light load current.

Digitized by Google

The air-gap has relatively but a small influence upon the leakage reactance R_s+R_r, but the reactance R_o depends directly upon the air-gap.

The ratio $R_o/(R_s+R_r+0{\cdot}004R_o)=\frac{167}{11{\cdot}3}=14{\cdot}8$ (Fig. 6).

In general, alternators have much larger air-gaps, and consequently much smaller ratios.

By making the air-gap of our machine four times as large, *i.e.*, by increasing it from 1·5 mm. to 6 mm., we find :

$k_1=32{\cdot}7/(2\times27{\cdot}7+\sqrt{6}(5+3))+19{\cdot}5/(2\times16{\cdot}5+\sqrt{6}(5+3))$
$=0{\cdot}525+0{\cdot}488$
$=1{\cdot}013,$

whence $R_\delta=195\times\frac{1{\cdot}1\times0{\cdot}15}{1{\cdot}013\times0{\cdot}6}=52{\cdot}8w,$

and $I_\delta=\frac{867}{52{\cdot}8}=16{\cdot}4$ amperes.

The leakage reactance of one phase of the stator becomes :—

$R_s=2{\cdot}98+0{\cdot}25+3{\cdot}1=6{\cdot}33w,$

and of the rotor, in terms of the stator :

$R_r=1{\cdot}67+0{\cdot}18+1{\cdot}6=3{\cdot}45w,$

whence $R_s+R_r=6{\cdot}33+3{\cdot}45=9{\cdot}78w.$

The current on light load for a pressure of 1,500 volts between phases will have the value :

$I_o=16{\cdot}4\times52{\cdot}8/(52{\cdot}8+6{\cdot}33)+5{\cdot}22\times34{\cdot}8/(195+6{\cdot}8)=14{\cdot}7+{\cdot}9$
$=15{\cdot}6$ amperes,

whence $R_o=867/15{\cdot}6=55{\cdot}5w.$

It follows that by quadrupling the air-gap the current on light load is augmented by $\frac{15{\cdot}6}{5{\cdot}22}=3$, and the short-circuit current by $\frac{86{\cdot}7}{76{\cdot}6}=1{\cdot}13$.

The ratio $R_o/(R_s+R_r+0{\cdot}004R_o)$ becomes 5·55 instead of 14·8 (Fig. 6).

We have already remarked in the previous article that the leakage reactance of the stator with the rotor removed is $10{\cdot}7w$, by chance the same value as with the rotor in position and short-circuited, the air-gap being 1·5 mm. We can, therefore, conclude that for this machine the short-circuit current at first increases with the air-gap, attains a maximum value, and then decreases so as to approach the original value with the rotor removed.

For an air-gap of 20 mm. we calculate :

$R_s=3{\cdot}21+0{\cdot}07+3{\cdot}1=6{\cdot}38w,$
$R=1{\cdot}785+0{\cdot}055+1{\cdot}6=3{\cdot}44w,$
$R_s+R_r=9{\cdot}82w.$

Our formulæ thus enable us to establish a minimum value for the reactance (λ_n increases more rapidly than λ_k decreases) but within these limits a great accuracy cannot be depended on, the permissible application depending upon the ratio $\frac{\tau}{\delta}$; since, for machines developed logically, the air-gap increases with the pole pitch, the formulæ can be applied in an almost general manner.

2. *Stator connected single-phase, two phases in series, rotor three-phase.*

The leakage reactance of the two phases of the stator in series is :—

$R_s=2\times6{\cdot}8=13{\cdot}6w.$

and of the rotor :—

$R_r=2\times3{\cdot}83=7{\cdot}66w,$

whence $R_s+R_r=13{\cdot}6+7{\cdot}66w,$
$=21{\cdot}26.$

The main reactance per phase corresponding to the air-gap :

$R_\delta=390w.$

The measured value of the magnetising current for a voltage of 1,740 was $I_m=5{\cdot}22$ amperes, whence $R_m=\frac{1,740}{5{\cdot}22}=334w$: there is thus a diminution of $(390+13{\cdot}6)-334=69{\cdot}6w$ corresponding to the reluctance of the stator and rotor iron. The current measured on light load with the rotor running at synchronous speed was $I_o=1$ 0·35 amperes for a voltage of 1,740 at the terminals, whence $R_o=168w$.

When the rotor is running at synchronism the alternating field of the stator is replaced by a rotating field, fixed relatively to the rotor.

By applying, then, 1,740 volts between phases at light load, the voltage per phase will be $\frac{1,740}{1{\cdot}73}=1{,}010$ volts instead of $\frac{1,740}{2}=870$ volts during magnetisation ; nevertheless, the flux has the same value in the two cases, the winding factors being 0·96 and 0·83, and $\frac{0{\cdot}83}{0{\cdot}96}=\frac{1{\cdot}73}{2}$.

By calculation we find for the light load current

$I_o=E_o/\left(\frac{R_m}{2}+\frac{R_s}{2}+\frac{R_r}{2}\right)$
$=1,740/(167+6{\cdot}8+3{\cdot}83)=1,740/177{\cdot}6=9{\cdot}8$ amperes,

in place of 10·35 amperes measured, including the watt component.

The current in the rotor, produced by the inverse field II., and hence of double frequency, will have the value :

$I_{r\pi}=10{\cdot}35\times\frac{552}{2\times80}\times\frac{2}{\sqrt{3}}\times\frac{1}{\sqrt{2}}=29{\cdot}2$ amperes ;

the measured value, including the watt component is 39 amperes.

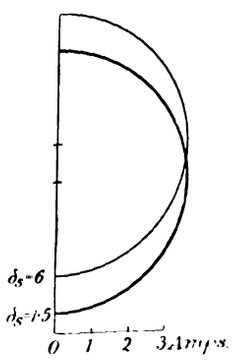

FIG. 6.

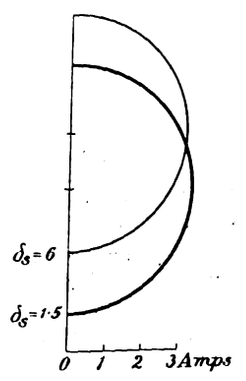

FIG. 7.

Here the ratio $R_o/(R_s+R_r+0{\cdot}004R_m)=168/22{\cdot}6=7{\cdot}5$ (Fig. 7).

By again increasing the air-gap from 1·5 to 6 mm. we find :

$R_\delta=105{\cdot}6w$ and $I_\delta=1,740/105{\cdot}6=16{\cdot}4$ amperes.

The leakage reactance becomes :

$R_s=12{\cdot}55w$ and $R_r=6{\cdot}38w$, whence $R_s+R_r=18{\cdot}93w.$

The magnetising current for a pressure of 1,740 volts will be

$I_m=16{\cdot}4\times105{\cdot}6/(105{\cdot}6+125{\cdot}5)+5{\cdot}22\times69{\cdot}6/(390+13{\cdot}6)$
$=15{\cdot}6$ amperes,

whence $R_m=1,740/15{\cdot}6=111w.$

With such an air-gap the increase in the reactance due to R_s, is more important than the diminution corresponding to the reluctance of the iron.

The light load current will have the value

$I_o=1,740/(55{\cdot}5+6{\cdot}27+3{\cdot}145)=1,740/64{\cdot}9$
$=26{\cdot}8$ amperes,

and $R_o=1,740/26{\cdot}8=65w.$

Thus, by quadrupling the air-gap the light load current is augmented in the ratio of $\frac{26{\cdot}8}{10{\cdot}35}=2{\cdot}58$, and the short-circuit current in the ratio $\frac{99}{77}=1{\cdot}17$; the ratio $R_o/(R_s+R_r+{\cdot}004R_m)$ becomes 3·4 instead of 7·5 (Fig. 7).

3. *Stator three phase, Rotor single phase, two phases in series.*

Readings were taken with various positions of the rotor, the two phases, II.-III. in series, being short-circuited.

These measurements give rise to the following interesting observations :—

1. By changing the position of the rotor the reactance per phase varies between that of the main circuit R_o and that of the leakage paths R_σ.

2. Although the current in phases II. and III. of the stator reaches the same maximum value I_{cc}, whilst the third phase I. is traversed by the magnetising current, the voltages per phase remain the same in value and in consequence retain a displacement of 120 deg.

3. The experiment shows that the E.M.F.s induced in the rotor phases are *independent* of its position with respect to the stator.

The distribution of the voltages over the various phases is explained as follows :—

(*a*) *Stator.*—We have already found that, on single phase one phase only with the rotor open, there is a mutual induction of 39 per cent. between neighbouring phases (Fig. 8). Now the magnetising current I_m is divided into equal parts between the phases II. and III., whence Fig. 9 and Fig. 10; by superposing Fig. 11 is obtained.

We thus deduce that the main flux induces in phases II. and III. E.M.F.s in phase with that of phase I., but of one-half the value; these E.M.F.s are thus displaced by 90 deg. with respect to the voltage $e_{II.-III.}$ applied to the terminals (Fig. 12). It follows that the short-circuit current corresponding to the leakage reactance of phases II. and III. in series, is displaced by 90 deg. with respect to I_m.

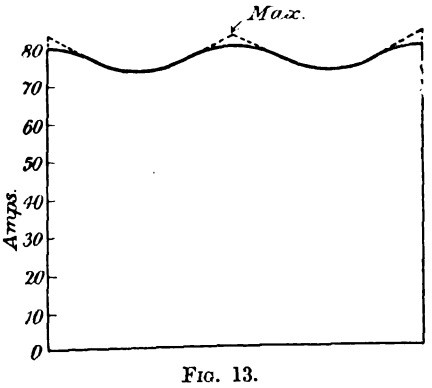

Fig. 13.

(*b*) *Rotor.*—In position (2), where the two short-circuited phases of the rotor are opposite two phases of the stator, the open phase of the rotor is opposite the third phase of the stator, which is then traversed by the magnetising current; the E.M.F. induced is therefore :

$$e_{o-I}=144\times\frac{40}{276}=20{\cdot}8 \text{ volts.}$$

The E.M.F.s induced in phases II. and III. will have one-half the value :

$$e_{o-II.}=e_{o-III.}=72\times\frac{40}{276}=10{\cdot}4 \text{ volts.}$$

and are in phase with the E.M.F. induced in phase I. The combined voltages will, therefore, have the value

$$e_{I.-II.}=e_{I.-III.}=20{\cdot}8+10{\cdot}4=31{\cdot}2 \text{ volts.}$$

Currents.—We have already found that the main reactance, single phase one phase only, corresponding to the air-gap, is $R_\delta=130w$. The current measured is $I_m=0{\cdot}92$ amperes for a pressure of 104 volts (Fig. 8), whence $\frac{104}{0{\cdot}92}=113w$; hence there is a decrease of $(130+6{\cdot}6)-113=23{\cdot}4w$ due to the reluctance of the iron.

The leakage reactance of two phases in series: $R_r+R_r-0{\cdot}004R_m=22{\cdot}6w$ whence $\frac{250}{22{\cdot}6}=11{\cdot}1$ amperes; the measured value was 11·55 for position (2) with the rotor and stator phases opposite each other. ($I_m/2=0{\cdot}46$ amperes is negligible

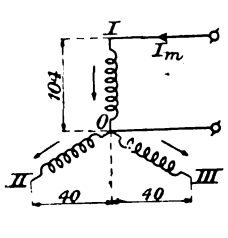

Fig. 8.

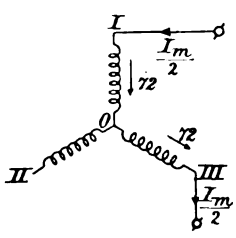

Fig. 9.

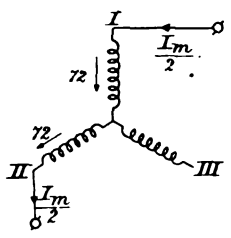

Fig. 10.

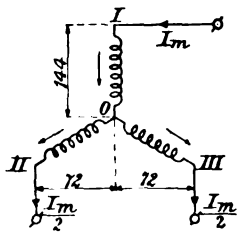

Fig. 11.

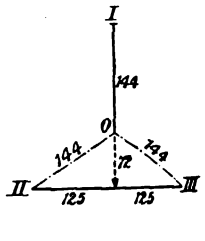

Fig. 12.

with respect to the short-circuit current I_{cc}, these two currents being displaced by 90 deg.)

We find for the rotor current

$$I_r=11{\cdot}55\times\frac{2\times276}{40}=80 \text{ amperes.}$$

Let us further verify the effective value of the currents when the rotor is slowly turned. The intensity of the current in each phase of the stator varies between 0·92 and 12·2 amperes, assuming that the variation is symmetrical and sinusoidal.

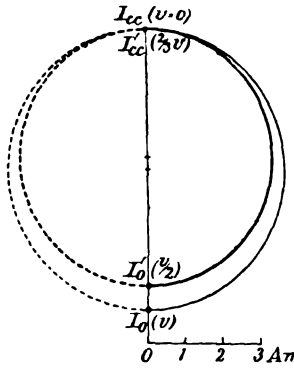

Fig. 14.

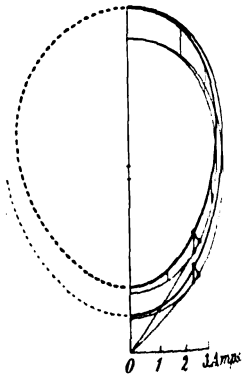

Fig. 15.

the mean value will be $\frac{1}{2}(0{\cdot}92+12{\cdot}2)=6{\cdot}56$ amperes, and the effective value

$$\sqrt{6{\cdot}56^2+\left(\frac{12{\cdot}2-0{\cdot}92}{2}\right)^2}=\sqrt{6{\cdot}56^2+5{\cdot}64^2}=8{\cdot}65 \text{ amperes.}$$

The effective rotor current is by experiment 77 amperes; this value is even inferior to the mean $\frac{1}{2}(73{\cdot}4-83)=78$ amperes. It follows that the variation is not sinusoidal and that the maximum values only occur momentarily (Fig. 13).

We now come to the diagram of operation at different speeds; we will utilise the formulæ already obtained to determine, as a check, the reactances, using the *mean* values found in the experiment—three phase

$$R_o=867/5{\cdot}2=167w;\quad R_{cc}=115/10=11{\cdot}5w.$$

(1) At speed v, $I_o=I_m=E_o/R_o=144/167=0{\cdot}86$ amperes; the value measured was 1 ampere.

Digitized by Google

(2) At speed $2v/3$, $I'_{cc}=E_o/1{\cdot}5R_{cc}=144/(1{\cdot}5\times11{\cdot}5)=8{\cdot}3$ amperes and $1{\cdot}11\ I'_{cc}=9{\cdot}2$ amperes; the value measured was 8·85 amperes.

3. At speed $\frac{v}{2}$:

$$I'_o=E_o/\left(\frac{R_{cc}}{2}+\frac{R_o}{2}+R_r\right)=144/\left(\frac{11{\cdot}5}{2}+\frac{167}{2}+0{\cdot}83\right)=\frac{144}{93.1}$$

$=1{\cdot}55$ amperes; and $(1{\cdot}11$ to $1{\cdot}5)I'_o=1{\cdot}72$ to $2{\cdot}32$ amperes the measured value was 2·05 amperes.

4. At speed $v=0$, $I_{cc}=I'_{cc}=8{\cdot}3$ amperes as with (2).

The rotor voltages have been measured between phases and between the terminals of the open phase; their variation in terms of the speed is interesting to notice. They diminish in a straight line law with increase of the speed as if the rotor were completely open, except between the speeds of 250 and 500 revolutions, where the voltages rise again and attain at 375 revolutions, a maximum value exactly the same as at standstill.

In fact, it is experimentally verified that at the synchronism of half-speed two fields show themselves in the rotor, each having the main value Φ; they rotate at a speed $v/2$ with respect to the rotor, the one in an opposite direction to the other. So far as the stator is concerned one of these two fields remains fixed and the other rotates in space at the speed v. It is this latter which produces the E.M.F. at the terminals.

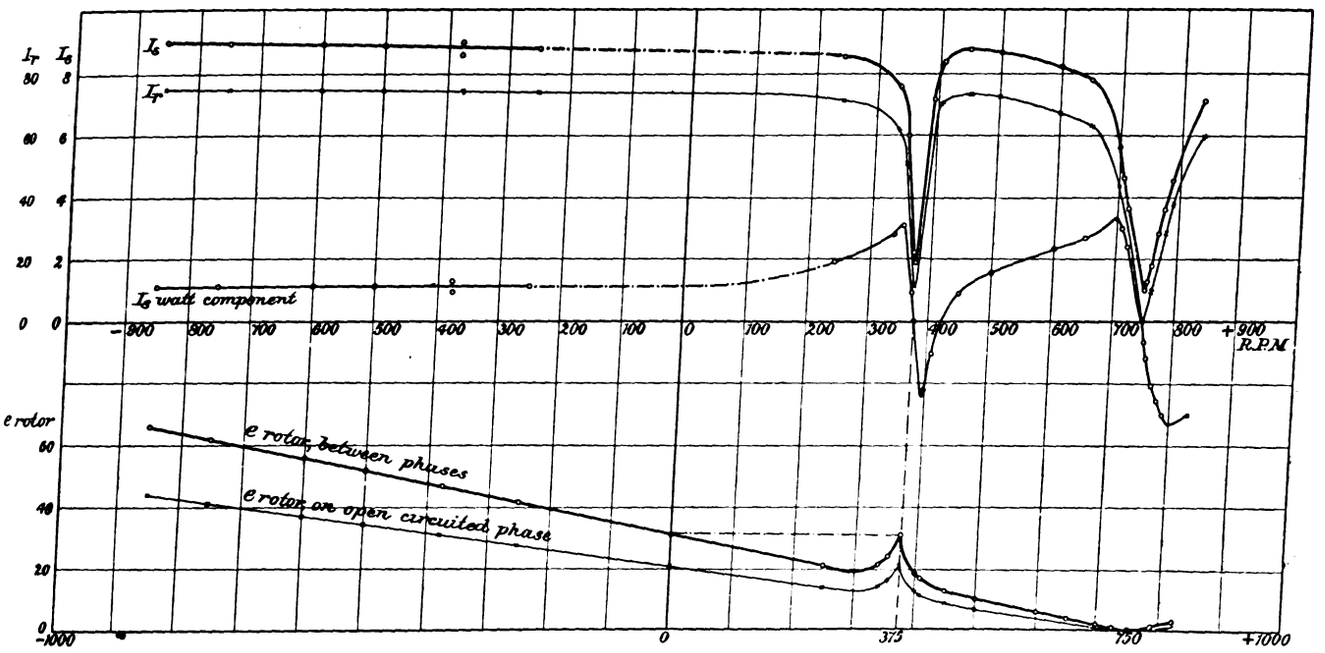

FIG. 17.

With these values we can draw the circles of the main currents and then construct the oval diagram of the resultant currents in the stator winding (Figs. 14 and 15).

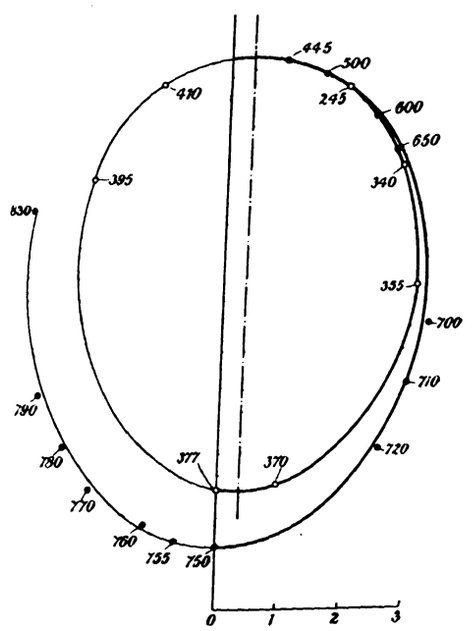

FIG. 16.

Experiments.—Complete measurements have been made on ie 175 H.P. motor with 250 volts between phases 50 ∽, the peed being varied progressively from −850 to +850 revs. per in. (Fig. 16); the voltage per phase retains the value $250/\sqrt{3}$ =145 volts at all speeds. The currents were measured simultaneously in two phases, also the watts per phase and the total atts; the readings have given entirely concordant results.

CHARGES FOR ELECTRICAL ENERGY SUPPLIED FOR TRACTION PURPOSES FROM COMBINED STATIONS.*

The joint Committee of representatives of the Incorporated Municipal Electrical Association and the Municipal Tramways Association (Messrs. J. Christie, S. L. Pearce, Thos. Roles, C. E. C. Shawfield, H. Talbot, S. J. Watson, T. P. Wilmshurst, and Messrs. H. E. Blain, J. Dalrymple, A. R. Fearnley, J. B. Hamilton, J. M. McElroy, Chris. J. Spencer) have very carefully considered the above question in all its aspects, and have come to the conclusion (subject to the reservations and general notes which follow) that the following broad principles should be adopted as the basis for the charge for electrical energy supplied for traction purposes from combined stations—viz.:

1. That the charge should be based upon the actual cost of production.
2. That in order to ascertain the actual cost of production it is necessary that the "standing costs" and the "running costs" should be properly

* Report drawn up by a joint Committee of the I.M.E.A. and M.T.A., and adopted by the I.M.E.A.

Digitized by Google

separated, and the following allocation is suggested subject to the general observations subsequently made in this report, viz. :—

	Standing costs. per cent.	Running costs. per cent.
Coal	25	75
Oil, waste and water	25	75
Repairs :—		
(*a*) Building	100	—
(*b*) Steam boilers, piping, &c.	75	25
(*c*) Engines and generating plant	50	50
Repairs of joint mains in case of high-tension stations	100	—
Wages at generating stations	50	50
„ sub-stations	100	—
Salaries of operating officials	100	—
Rents, rates and taxes on joint assets (not including income tax)	100	—
Management expenses (salaries of administrative officials)	50	—
Interest in respect of all capital which is used in common for the various classes of supply	100	—
Depreciation in respect of all assets used in common for the various classes of supply	100	—

3. That the tramways department's proportion of the standing costs should be the ratio which the maximum demand for traction purposes at the generating station bears to the total maximum demand on the generating station, such maximum being arrived at in the same manner in each case as hereinafter set forth.

4. That the tramways department's proportion of the running costs should be the ratio which the total number of units delivered to feeders at the station for traction purposes bears to the total number of units delivered to feeders at the station for all purposes.

5. That the traction maximum demand should be taken to be the mean of the figures representing: (1) The maximum traction demand at any time of the year, and (2) the average of the daily maximum traction demand (Sundays excepted) taken over a period of a month coincident with the maximum demand on the station.

The method of ascertaining the traction maximum shall be taken as the maximum observed load, deducting therefrom 20 per cent.

6. That in cases where storage batteries are in use the figure to be adopted as the traction maximum demand and used for allocating to the tramways department their proportion of the standing costs under the headings of (*a*) rents, rates and taxes, and (*b*) management expenses, should be the generating plant maximum plus the battery; and for the purpose of allocating the remaining standing costs—*i.e.*, (*a*) coal, (*b*) oil waste and water, (*c*) repairs, (*d*) wages at generating and sub-stations, and (*e*) salaries of operating staff—the maximum demand to be adopted should be the maximum demand of the generating plant only.

That the two-hour rating of any storage battery should be deemed to be its kilowatt capacity, and that all repairs to the battery which could be used for the dual purpose of lighting and traction should be dealt with in the same manner as repairs to engines and generating plant. If, on the other hand, it is put in for purely traction purposes, it should be dealt with under the heading of repairs to exclusive traction plant.

7. That the total costs in respect of traction feeders and any other apparatus connected exclusively with traction distribution should be wholly allocated to the tramways department, such costs to include interest, depreciation and repairs.

8. That it is desirable, as a matter of ordinary commercial prudence, that there should be established in connection with electrical undertakings a suitable reserve fund for meeting any extraordinary expenditure in any year, and that the tramways department should bear their proper proportion of the annual sums to be set aside for establishing such reserve fund, but it should be an understading that the tramways department should be a party to the fixing of the annual amounts to be so set aside.

9. That the total actual cost of production of current for traction purposes may be summarised under the following heads—viz. :

(*a*) Proportion of standing costs (ascertained as per paragraphs 2 and 3)
(*b*) Proportion of running costs (as per paragraphs 2 and 4).
(*c*) Total cost of traction feeders, &c. (as per paragraph 7).
(*d*) Proportion of reserve fund (as per paragraph 8).

10. That the question as to what amount of profit (if any) should be paid to the electricity department by the tramways department is a matter which each municipality should settle for itself. The joint Committee have only endeavoured to lay down what they consider to be the correct method of ascertaining the actual cost of production, and upon which they suggest the charge should be based.

General Notes made by the Joint Committee.

Coal Allocation as between Standing and Running Costs.—The question as to the proper proportion of coal to be allocated to the standing costs received careful consideration by the joint Committee. From the evidence in their possession it would appear that the amount of coal which is consumed to make up for radiation losses differs somewhat in the various stations. The general information obtained showed that it averages from 4 lb. to 5 lb. per kilowatt of plant usefully employed per day. It is suggested by the joint Committee that each municipality should carefully go into this matter, with a view to ascertaining, as far as possible, the actual figure for their particular station. If, however, it is not thought worth while in any particular case to go into this detail, it is suggested that the division suggested by the joint Committee should be adopted—viz., 25 per cent. to standing costs and 75 per cent. to running costs.

Oil Waste and Water.—The joint Committee, after considering the allocation under this head, suggests that it should follow the division proposed in the case of coal. They recognise that this may not be strictly accurate, but they think that the smallness of the figure does not justify a different allocation.

Repairs to Steam Boilers, Piping, &c.—The figures suggested as the allocation under this head are not less than 75 per cent. to standing costs, the balance going to running costs. The joint Committee suggest that the figures should be settled for each station having regard to local conditions.

Salaries of Operating Officials.—Under this head it is suggested that only the salaries of those officials should be included whose services are devoted to generation and transformation of electrical energy.

Management Expenses (Salaries of Administrative Officials).—Under this head the proposal is to include the salaries of the administrative staff as apart from the staff engaged at the generating station. It would include the salary of the chief engineer, the secretary, the accountant and officers of that class. It will be observed that it is proposed to allocate only half of the management expenses to standing costs, the remaining half having no connection with the traction supply is eliminated from the calculations.

Interest and Depreciation.—The capital, it is suggested, should be that which is used *in common* for the various classes of supply, and should be ascertained by taking the total capital expenditure of the undertaking and deducting therefrom all items which are *not* used in common—as traction feeders, lighting feeders and distributing networks and services, meters, &c., motors (for hire), any other plant not used for the common supply.

In calculating the depreciation charges it is suggested that the "lives" of the various portions of the assets should be fixed in accordance with the actual provision made by the electricity department.

Method to be adopted for Accurately Measuring the Current Supplied for Traction Purposes.—The joint Committee suggest that all direct-current meters should be of the watt-hour type. When fixed in position where they are liable to be affected by stray magnetic fields they should be astatic, and of a type containing no iron or permanent magnets, and should not be affected by momentary overloads or short-circuits. Where meters containing permanent magnets or iron are used it is advisable that they should be shielded as much as possible.

It is further desirable that all meters should be calibrated for the temperature of the surrounding medium in which they will be located. For loads up to 2,000 amperes the total current type is recommended, and above this output the shunted type—each with its own shunt.

Where polyphase currents have to be measured "dynamometer" or "induction" type of meters may be used.

It is suggested that the two-wire wattmeter method should be employed as being the most satisfactory way of metering three-phase electrical energy.

The joint Committee recommend, having regard to the importance of reliable measurements being obtained, that in all generating stations three wattmeters should be arranged in series. One meter being the property of the tramways department.

In all important sub-stations they consider two wattmeters will suffice, one of which would also be the property of the tramways department.

Provision should be made for reference to an independent authority in the event of any dispute arising as to the accuracy of any or all of the meters installed.

Reservations Made by the Joint Committee.

Traction Maximum Demand.—The joint Committee in paragraph 5 have suggested a method of ascertaining the traction maximum which they are of opinion could be equitably applied to the majority of tramway undertakings in the kingdom; they consider, however, that it might not be applicable in every case where the "peaks" are accentuated or where the ratio of $\frac{\text{sustained maximum demand}}{\text{average maximum demand}}$ is of an abnormally high value, due to (*a*) geographical or (*b*) service conditions. As an instance of the former, they cite the case of those towns having very severe gradients on their system, and as an instance of the latter the case of those towns having to deal with football or other abnormal rush traffic.

Capital Charges.—The joint Committee have set forth in paragraphs 2 and 3, and further amplified in the "General Notes," what they consider the most practicable method of treating the question of the capital charges in the ascertainment of the costs of traction supply. They are aware, however, that circumstances may arise in connection with the development of electrical undertakings which might properly justify some departure from the method suggested.

They have had under their notice the case of stations where the principle of dealing with the capital charges on the "common plant" basis or the "pooling system," as it may be termed, would *not* be in the best interests of either the electricity or the tramways undertakings. They therefore suggest the following as an alternative basis which might be applied in cases which come within this category—viz. :

(*a*) That the tramways department's proportion of the charges for interest on capital expenditure in respect of generating and transforming plant and boilers should be based upon the cost per kilowatt for such plant at the time of its installation, the amount of such plant to be ascertained on the maximum demand principle already described, plus a reasonable allowance for reserve or spare plant to be determined in accordance with the local conditions.

Digitized by Google

(*b*) That the tramways department's proportion of the interest on the capital in respect of land and buildings should be based upon the proportion which the kilowatt capacity of the traction plant bears to the total kilowatt capacity installed.

(*c*) That the depreciation charges should be determined in accordance with the paragraph under the heading of "General Notes" contained in this report.

The joint Committee cannot make any recommendations as to which of the two methods outlined should be applied in any particular instance. Each case should be settled on its merits, having regard to the local conditions, and, in the event of any dispute arising, the joint Committee suggest that provision should be made for referring the matter to an independent engineer for settlement.

The joint Committee desire to take this opportunity of acknowledging the special assistance which they have received in the work of drafting the report on this difficult matter from the sub-committee, consisting of Mr. S. L. Pearce (Manchester) and Mr. T. Roles (Bradford), representing the I.M.E.A.; and Mr. J. M. McElroy (Manchester) and Mr. C. J. Spencer (Bradford), representing the M.T.A. These gentlemen have devoted a considerable amount of time to the question, and it is largely owing to their efforts that your Committee are able to report at this date.

SOME NOTES ON ELECTRIC FURNACES.

BY J. HÄRDÉN.

The valuable contributions by Mr. Carl Hering, which have appeared from time to time in THE ELECTRICIAN on the subject of the design of furnace electrodes, have no doubt been welcomed by designers. Many difficulties, indeed, confronted the designer in the early days of electric furnaces, both as regards the best size of electrodes and the most efficient way of arranging them, and also, last but not least, where to get them.

Some 12 years ago the author had to design a graphitising furnace for carbon rods in Russia. The electric power available was direct current, about 3,000 amperes at 65 volts, no alternating current being obtainable at the works in question. The furnace was to be operated in series with a row of electrolytic cells and intended to absorb surplus power in a useful way. The carbon rods to be graphitised were about 3½ in. diameter by 4ft. long. Owing to these two facts the operation could not be carried out "in bulk," as is the practice at Niagara, but had to be a continuous operation. It was found subsequently that the best method under the circumstances was to pass three rods at a time slowly through the furnace.

At first, attempts were made to produce a large arc in a carbonaceous atmosphere. This method had, for obvious reasons, to be abandoned very soon. The arc behaved very well for 6 to 8 hours, but as soon as the interior of the furnace got well heated the furnace walls became part of its path, being conductive at that temperature, and even directing magnets had no beneficial influence owing to the irregular paths taken by the arc. Also, the rods to be treated got scorched and injured by the action of the arc.

In this connection it might be mentioned that the suggestion made by A. Mahlke, in "Met. and Chem. Eng.," Vol. IX., No. 1, p. 42, to broaden the active ends of the electrodes, so as to obtain a better distribution of the arcs and the heat in the furnace is not likely to be successful. Anyone who has had an opportunity to observe the arc, even in a furnace of the largest size, will have noticed how the base of the arc is always concentrated on a comparatively small area, which wanders about on the surface of the electrode. This is no doubt due to the fact that the arc requires carbon vapour of high temperature (or any other ionised medium of high temperature), and as this cannot take place at the same instant over the whole surface of the electrode, the arc will always be concentrated at its base. The same may also be observed in a mercury-vapour lamp; the arc forms only a comparatively small spot on the surface of the mercury cathode.

Reverting again to the graphitising furnace a further attempt was made to convert it into a resistance furnace in the following way: Two electrodes, about 6½ in. square, were placed inclined on opposite sides in the furnace chamber of firebrick. The bottom consisted of electrode stumps and stamped coke. The furnace was partly filled with granular charcoal, in which the electrodes were embedded about 7 in. or 8 in. Due provision was taken to prevent the current passing through the furnace walls, an arrangement similar to that used in the pig iron smelting furnace by Gronwall & Stalhane.

This arrangement would work satisfactorily for about a day or so; after that period, however, trouble began. In spite of the air being excluded as far as possible from the electrode collars the electrodes were consumed very rapidly just inside the furnace, while the active ends grew in thickness by the deposit of carbonaceous matter to such an extent that the electrode took the shape of an irregular mushroom, causing great difficulties in the regulating.

A final alteration was then made, which proved successful. The bottom of the furnace was built up on a hollow cast-iron plate, similar to that in a carbide furnace, two of which were also in operation at the works. Electrode stumps about 8 in. high were placed in carbon cement on the iron plate and the brickwork erected to form the furnace chamber. This bottom plate formed the positive electrode, while the negative one consisted of a 6½ in. by 6½ in. carbon suspended from above, by means of a water-cooled holder, through an opening in the furnace roof. The furnace chamber was filled with granular charcoal as before, in such a manner as to reach the upper electrode and sloping down at the sides, which prevented the current passing through the walls. The rods to be graphitised were passed three by three slowly through the glowing mass of charcoal, and allowed to cool in coal dust on a gantry. The rods were examined as to the degree of graphitising by tapping with a steel bar; the sound emitted gave a good idea of the process. Also the polishing effect was ascertained by rubbing.

One difficulty remained to be solved; the roof was soon destroyed in each case, and we may assume that this difficulty is still a great stumbling block, even to-day, in all electrode furnaces. In the above instance, the problem was solved in this way: The roof of the furnace was protected by means of scrapped or curved carbon electrodes, separated and held by means of wedge-shaped high-grade fire bricks, to prevent leakage of current. After some adjustment this type of roof could be made to last for 8 or 9 months, even when run continuously day and night at a very high temperature, and despite the fact that the furnace was emptied and recharged every 24 hours, a considerable fall in temperature taking place during this process; in fact, this refilling was the primary cause of the rapid breakdown of the original brick roof. One top electrode would, under these circumstances, last four to five days, its dimensions being, as already stated, 6½ in. by 6½ in by 4 ft 6 in., and the current 3,000 to 3,500 amperes at 40 to 45 volts. As far as known to the author the bottom needed no repair at all during four years.

A curious incident during the trials with the arc design led to a number of further experiments and also some patents. When the large arc was started, violent rushes of current took place, the whole furnace being cool. This was strongly objected to at the power station, as it caused considerable surging between the large engines running in parallel—the regulating device of the steam engines was of such nature as to be particularly sensitive in this respect.

While awaiting the construction of a suitable starting resistance (an iron band immersed in running water) a makeshift was employed to start the arc, and also to prevent it extinguishing. This consisted of a spark coil, made to discharge between the electrodes. In order to prevent the spark taking any other way than was intended, a condenser was connected to the sparking circuit and a primitive inductance in the power circuit. By this means it was possible to start the arc without any serious current rush, and the tendency of the arc to go out before the furnace was heated ceased, if the spark was kept going.

This device was first tested with a smaller arc and narrower electrodes. It was then observed that the tips of the electrodes got more quickly graphitised and that the graphite formed was of a more flaky appearance when the spark had been in operation for some time, but only under certain conditions. The whole phenomenon was at first thought merely to be accidental, but on further investigation it was found that the graphitising could, under favourable conditions, be somewhat

Digitized by Google

accelerated by introducing condenser discharges of practical magnitude. A specially made spark coil and a suitable condenser were, therefore, installed and put into permanent use. The workmen were protected from the discharge by means of thick mica shields surrounding the auxiliary electrodes through which the discharges were introduced into the furnaces.

Other and more pressing work prevented a more systematic and exhaustive investigation as to the efficiency of the methods. It may be said, however, that its use appeared to be justified. The workers, a man and a boy per shift, were paid by piecework for a minimum number of rods, passed by the foreman after each shift, and an additional bonus for each extra rod passed. It was regularly found that if the spark coil had been out of operation for some time during a shift the number of rods passed decreased, and the rejected rods had to be sent through the furnace again, therefore the workmen showed a keen interest in keeping the coil in working order.

As there was no alternating current available at the works, the coil had perforce to be operated by direct current at 125 volts. Anyone who has had the task of keeping a large coil, giving a heavy 12 in. to 14 in. spark in operation day and night without breakdown for several months at a time will testify that the finding of a suitable interrupter is by no means an easy problem. At first, the ordinary mercury make-and-break, consisting of two motor-driven vertical pins was tried, but it was soon found that this did not answer. The pins were rapidly worn out, regardless of the metal used; besides, the mercury soon clogged in spite of a thick strata of oil over it. Carbon rods lasted longer, but the spark was greatly diminished, owing to insufficient rapidity of break.

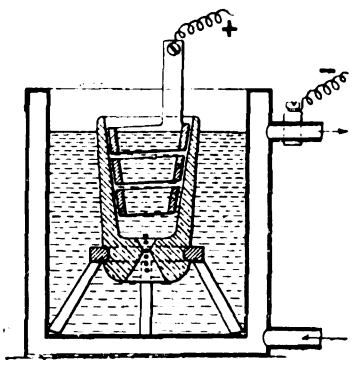

FIG. 1.

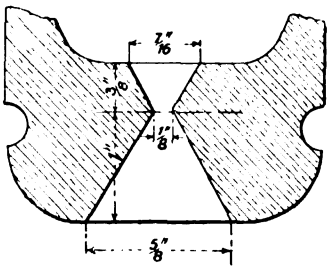

FIG. 2.

A turbo-interrupter was then tried in which a mercury jet was projected in the well-known manner against a toothed iron wheel, moving in oil or cooling liquid. Even this proved futile, as the teeth of the wheel were soon worn off by the sparking, and the mercury got so clogged in three to four days that it had to be replaced. To prevent this latter nuisance a jet of coal gas was introduced into the vessel, so as to prevent oxidation; but even this measure, though it did some good, did not sufficiently reduce breakdowns.

The electrolytic interrupter was finally resorted to and, in spite of its low electric efficiency, proved to be more satisfactory than the others. A platinum point, as introduced by Dr. Wehnelt, was first tried, but was soon destroyed by the current. After a good deal of experimenting it was found to answer the purpose best if a large porcelain insulator drilled through the top, without any metal point at all, was used.

As indicated in Fig. 1 the insulator was suspended in a double-walled vessel of lead, cooled by running water. A lead spiral formed the inner, or positive electrode; the active liquid was sulphuric acid of about 1·14 specific gravity. The paper condenser in the base of the coil was not in circuit while this interrupter was at work.

With this device it was found quite possible to keep the coil going day and night for many months, only stopping about every fifth day for cleaning and replacing of the acid, which was gradually vaporised, but such stoppage only required about 15 to 20 minutes. The hole drilled in the insulator was gradually widened by the action of the current. It had to be replaced about every three months, for which purpose a spare one was always kept.

At first some difficulty was found in the tendency of the apparatus to act as a pump. In some cases the acid was driven out through the bottom hole into the outer vessel, causing the working to be irregular and producing much heat. Again, with another insulator substituted, the acid rose in the inner room so as to overflow and cause a short-circuit. It was soon found that the shape of the hole was responsible for this behaviour. If the hole sloped too much upwards the gas bubble causing the interruption exploded upwards, thus driving the pile of liquid up into the inner vessel, causing a surging from underneath, so that the liquid in the outer vessel rushed inwards. If this happened rythmically, as was often the case, the insulator was soon filled to overflowing. On the contrary, if the boring widened too acutely downwards the bubbles burst outwards and drove the liquid into the outer vessel.

In Fig. 2 is indicated the correct shape of the boring, with which no surging took place. The hole should be well polished, or preferably glazed, when the action is much minimised. The period of interruption was adjusted by means of a variable inductance in the primary circuit, so as to give the best effect. Large glass condensers were used in the secondary circuit to produce the oscillations necessary. With this arrangement the breakdowns were very rare, and the whole apparatus could be left for four to five days without inspection.

NEW ELECTRICITY SUPPLY STATION FOR EGHAM AND STAINES.

The laying of the foundation stone of the power station by the Rt. Hon. Sir T. Vezey Strong (Lord Mayor of London), on Saturday last, marks the inception of the last stage in the provision of a public supply of electricity in the districts of Egham and Staines, two small county towns on the banks of the Thames some 20 miles from London.

The history of the supply really starts in the year 1904, when Mr. Powell erected a small power station on premises in the rear of High-street. From this station current has been supplied down to the present time to a number of the principal shops and places of amusement in Egham. In 1907 statutory powers were obtained, subject to the undertaking, within a period approved by the Board of Trade, being transferred to a limited company.

At this juncture Messrs. Handcock & Dykes were retained to advise on the development of the undertaking; and as the question of a public supply of electricity in Staines was becoming a pressing matter, and it was obviously to the advantage of both districts that their supply should be from one source, a further provisional Order to cover the Urban District of Staines was obtained in 1909.

All the powers obtained were then transferred, with the consent of the Board of Trade, to the Egham & Staines Electricity Co., as the new company is called.

A suitable site for the generating station having been found nearly midway between Egham and Staines, Messrs. Handcock & Dykes were instructed to complete their plans, which were for a high tension scheme and a Diesel-engine station, and to apply for the approval of the Board of Trade to the system proposed, the latter as mentioned below, containing some novel features entailing special consideration on the part of the Board. On this approval being obtained, specifications were prepared, and early in 1911 tenders were invited for the necessary works.

Under the new Electric Lighting Act, notices were served on owners of property in the neighbourhood of the proposed site of the generating station, and unfortunately some objections were made, thus rendering it necessary for the Board of Trade to hold an inquiry. This could not take place before July 19, and, meantime, neither the building of the station nor the erection of the machinery could be proceeded with, thus rendering it impossible for the station to be erected in time to supply current, as hoped, early in September. The result of the inquiry was, however, favourable, and immediately on receiving the authorisation of the Board of Trade in August, not a moment was lost in commencing the erection of the buildings. It is expected that the station will be complete, ready to commence the supply of current some time in December next.

The station, far from being a detriment to the surrounding

Digitized by Google

property, will be a distinct addition from an architectural point of view. The absence of any chimney shaft and of any dust and dirt, secured by the use of Diesel oil engines, gives the whole an appearance which compares very favourably with that of the gas works that are on an adjacent site.

The first instalment of plant will consist of two Diesel-type crude oil engines, each direct coupled to a 100 kw. 2,000-volt single-phase Crompton alternator with direct-coupled exciter. The engines are of the vertical three-cylinder type, running at 250 revs. per min., and have been made at Messrs. Mirrlees, Bickerton & Day's works. The circulating water for cooling the cylinders will be passed through one of Little's patent water coolers.

The main switchboard, which is now on view at the Electrical Exhibition at Olympia, is of the most modern high-voltage cellular type, made by The Electric & Ordnance Accessories Co., and consists of six enamelled slate panels carrying the necessary instruments and handles for operating the high-tension switchgear fitted in fireproof cubicles behind the panels.

The system of distribution consists of paper-insulated lead-covered and armoured high-tension concentric cables laid in the ground, some seven miles having already been laid. At central positions in both Egham and Staines transformer kiosks have been erected in which the high-tension current will be transformed down to a pressure of 100 volts, and distributed throughout the principal streets by about 4 miles of low-tension three-wire cables.

Under the system approved by the Board of Trade the low-tension mains may either be ordinary armoured cables laid underground or special metal-sheathed conductors fixed on the fronts of the houses, thus obviating the necessity for opening up and disturbing the foot-paths whenever a new service is required, and enabling a supply to be given in certain cases where otherwise the demand would not be sufficient to warrant the cost of extending the underground mains. In other portions of the district houses will be supplied direct through transformers fixed in the houses themselves.

One of the most interesting features of the supply is that with the special permission of the Board of Trade one pole of each consumer's supply is "earthed" in the house fuse box, so that if desired the "earthed concentric" or "single wire" system of wiring can be adopted without having to interpose a double-wound transformer between the consumer's installation and the supply mains. By adopting this system only one insulated wire is required instead of two, and only single-pole main switches and distribution fuses are necessary, thus admitting of a considerable reduction in the cost of house wiring.

In accordance with the Board of Trade requirements a removable link is fitted in the house fuse boxes to connect one pole of the main service cable to the "earthed" terminal of the fuse box (this terminal is fixed direct on to the case of the fuse box), and thus to the lead and outer armouring of the mains, so that by removing this link the continuity of the return can be tested at any time exclusive of any leakage through earth.

A flat rate of 6d. per unit has been adopted, and there is also an alternative method of charging which is expected to prove very popular. For a slight additional meter rent, a special two-rate meter will be fitted and current supplied at the low price of 2d. per unit for all purposes whether the energy be used for lighting, heating or power, except during three hours per day, when the price will be 7d. per unit. The time when the three-hour period commences, varies from about 5:30 p.m. on the shortest day to 7:30 p.m. on the longest.

The feature of this system of charging is that separate wiring is not required when it is desired to connect up heating and cooking utensils, whilst the low rate of 2d. per unit encourages the long use of lights in bedrooms, passages, &c., during the night time, and also outside shop windows until a late hour in the evening. If desired also, a fixed price per lamp will be quoted, the charge for small installations of only a few lights being approximately 2½d. per lamp per week.

At the present time the applications for supply represent about 60 kw., so that by the time the station is completed the plant should be well loaded. Mr. F. W. Strickland has been appointed engineer and manager, and has already taken up his duties.

At the laying of the foundation stone last week, Mr. A. H. Dykes explained the main features of the scheme. The presence of the Lord Mayor of London attracted a considerable number of sightseers, and in spite of the stormy weather, the ceremony was a great success.

The Lord Mayor, in responding to a vote of thanks moved by Mr. W. A. Schultz, J.P., said that in his opinion an undertaking such as that at Egham should be run at the expense and risk of the individual, and not of the State. He also considered that in an enterprise of this character the best results are obtained, and the largest economies effected, when it is controlled by individuals who are prepared to take considerable financial risks.

THE BALLOON AS A WIRELESS TELEGRAPH RECEIVING STATION.*

BY P. LUDEWIG.

As very little has been published regarding the wireless stations which are fitted on balloons, the author determined to describe some tests on this subject made by him at the beginning of the year. The object of these tests was to pick up with the simplest arrangement of apparatus the waves sent out from wireless land stations.

The crux of the problem lay in the arrangement of the antenna, which was made in two parts, between which the receiving apparatus was connected. As regards the receiving apparatus itself, a choice was made of those employed in practice.

The following was the arrangement employed: When the balloon was half filled a wire was wound round the equator of the gas bag, being interwoven through the protecting cordage; and the end of the wire was placed in the basket. This wire formed the upper half of the antenna. To form the lower half a heavy wire was dropped from the basket after the balloon had risen. Fig. 1 shows the completed arrangement.

As the object of the tests was to discover with how simple means picking up of messages was possible, a very simple apparatus was chosen. A Schlömilch cell was used as receiver, and this was connected direct to the antenna, as shown in Fig. 2, in order that the room taken up should be as little as possible. With this arrangement accurate tuning was, of course, impossible. Approximation

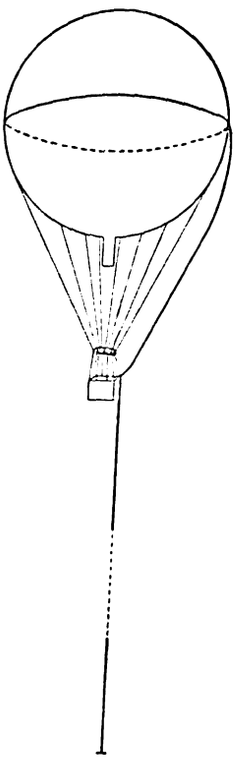

FIG. 1.

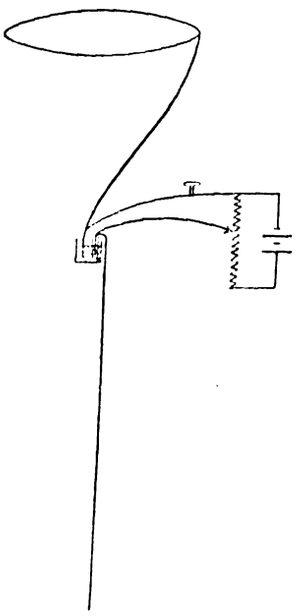

FIG 2.

to the wave length of 500 metres at the sending station was obtained when the wire from the basket was 125 metres long, or equal to $\lambda/4$.

The choice of some simple receiving station also solved the problem as to whether damped or undamped waves should be used for sending, the small tuning capacity of the receiving station making the use of the first-named a necessity. As sending station the 30 m. (100 ft.) high "T" antenna at the Electrotechnical Institute of the Frankfort Physical Society was used. This station employs the Braun method, highly damped waves with close coupling being used.

During the first tests in March, 1911, which lasted two hours, the balloon was 50 km. (31¼ miles) away at a maximum height of 600 m. (2,000 ft.) from the ground. At this height the signals received were not so clear as when the balloon was lower down.

During a second test on March 23rd three balloons were used, the stations at Göttingen, Darmstadt, Karlsruhe and Frankfort being employed for sending. The first three of these transmitted singing sparks, the latter working on the Braun system with a frequency of 50. The signals from Frankfort and Darmstadt were heard quite easily, but the other two could not be heard. During the time Göttingen was sending, signals with a frequency of 50 were received, and a message was received so quickly as to be unintelligible. Subsequent inquiries show this to have been transmitted from the balloon belonging to the Telegraph Battalion at Coblentz.

The Rates for Subscription to "THE ELECTRICIAN" are as under:—

	Year.	Half-Year.	Quarter.	
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.	Post free, payable in advance.
Canada	28s. 3d.	14s. 6d.	7s. 6d.	
Postal Union ...	30s. 0d.	16s. 0d.	8s. 0d.	

New volumes of "THE ELECTRICIAN" commence in April and October.

(This charge includes all the numerous Supplements.)

Vols. I to LXVI. can now be supplied. Price on application.

"THE ELECTRICIAN" SERIES OF STANDARD ELECTRICAL BOOKS

can be obtained of all Booksellers at Home, in the Colonies, and Abroad.

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. Published annually in February, corrected to mid-February. Established 1882. A very valuable advertising medium, covering the entire Industry. SUBSCRIPTION Price (which is received *in advance* up to Jan. 31st in each year for the next following edition) 8s 6d. nett, postage 9d. extra. Published price 15s. nett, postage 9d. extra. Postage to British Colonies, 2s; Europe, 2s; U.S.A., 3s. 6d.; other countries, 2s. 6d. *Digest of Contents of the 1911 Edition sent free on application.*

THE PRACTICAL WIRELESS SLIDE RULE. By Dr. H. R. Belcher-Hickman. Price 2s. 6d. nett. *Reduction on quantity.*

LIVINGSTONE'S DIAGRAM FOR THE EASY CALCULATION OF SHAFT AND BEAM DEFLECTIONS. By R. Livingstone. 2s. 6d. nett. By post in tube, 2s. 10d.

"THE ELECTRICIAN" PRIMERS (31 Primers in all, and a GLOSSARY). Single Primers 3d. each post free. *New and Enlarged Edition in One Complete Vol. or Three Separate Vols.* FULL PROSPECTUS FREE.

ELECTRIC TRACTION ON RAILWAYS. By Philip Dawson. Price 25s. nett. *Prospectus free.*

ALTERNATING-CURRENT MOTORS. By Dr. Rudolf Goldschmidt. Price 6s. 6d.

THE SHOT-FIRER'S GUIDE: A Practical Manual on Blasting and the Prevention of Blasting Accidents in Mines, Quarries, &c. By W. Maurice. Price 3s. 6d. nett.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. Wilkinson, M.I.E.E. *New Edition.* Now ready. Price 15s. nett.

ELECTRIC BLASTING APPARATUS AND EXPLOSIVES: With Special Reference to Colliery Practice. By W. Maurice. Price 8s. 6d. nett.

THE ELECTRIC FURNACE IN IRON AND STEEL PRODUCTION. By John B. C. Kershaw, F.I.C Price 3s. 6d. nett.

BRAKES FOR TRAMWAY CARS. By H. M. Sayers. Price 3s. 6d. nett.

THE MECHANICAL DESIGN AND CONSTRUCTION OF COMMUTATORS. By R. Livingstone. Price 6s. nett.

THE ALTERNATE-CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. [abroad 13s.

VOL. I.—Price 12s. 6d. post free, abroad 13s. VOL. II.—Price 12s. 6d. post free, abroad 13s.

HANDBOOK OF THE ELECTRICAL LABORATORY AND TESTING ROOM. Very fully illustrated. By Dr. J. A Fleming. Vol. I., 12s. 6d. nett, Vol. II., 14s. nett.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. Fleming. 6s. nett.

ELECTRICAL LABORATORY NOTES AND FORMS. Arranged by Dr. J. A. Fleming, M.A., F.R.S. Single copies 4d. nett, or in dozens at 3s. 6d. nett. Complete Sets of 50 Notes and Forms, 12s. 6d. nett, or in strong portfolio, 14s. nett; or bound in strong cloth, 15s. nett. Spare Copies of Tabular Sheets, 1s. per dozen. Portfolios, 1s. 6d. each. Sectional paper, 1s. per dozen sheets. *Complete Prospectus post free on request.*

ELECTRICITY METERS: THEIR CONSTRUCTION AND MANAGEMENT. By C. H. W. Gerhardi. Profusely illustrated. Price 9s. nett.

ELECTRICITY IN HORTICULTURE. By Prof. S. Lemstrom. Illustrated. 3s. 6d nett.

RADIO-ACTIVITY: AN ELEMENTARY TREATISE FROM THE STANDPOINT OF THE DISINTEGRATION THEORY. By Fredk. Soddy, M.A. Fully illustrated. Price 6s. 6d. nett.

ELECTROMAGNETIC THEORY. By Oliver Heaviside. Vol. I. Price 12s 6d. Vol. II. Price 12s. 6d. *Vol. III. in the press.*

MOTIVE POWER AND GEARING FOR ELECTRICAL MACHINERY. By E. Tremlett Carter, C.E., M.I.E.E. Revised by G. Thomas-Davies, A.M.I.E.E., F.C.S. Price 12s. 6d. nett.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. Ewing, B.Sc., F.R.S., F.R.S.E. Price 10s. 6d.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. Kennelly and H. D. Wilkinson, M.I.E.E Price 6s. 6d.

ELECTRIC MOTIVE POWER. By Albion T. Snell. Price 10s. 6d. nett.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. Geipel and H. M. Kilgour. Price 7s. 6d. nett.

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. Elton Young. Price 10s. 6d.

STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By H. K. C. Fisher and J. C. H. Darby. Price 7s. 6d. nett.

SIGNALLING ACROSS SPACE WITHOUT WIRES: THE WORK OF HERTZ AND HIS SUCCESSORS. With new Chapter on Tuning. By Dr. Sir Oliver J. Lodge. Price 5s. nett.

THE ART OF ELECTROLYTIC SEPARATION OF METALS. By Dr. G. Gore, LL.D., F.R.S.

ELECTRO-CHEMISTRY. By Dr. George Gore. Price 2s. [Price 10s. 6d.

BEGINNER'S MANUAL OF SUBMARINE CABLE TESTING AND WORKING. By G. M. Baines. Price 7s. 6d. nett.

CARBON MAKING FOR ALL ELECTRICAL PURPOSES. By Francis Jehl. Price 10s. 6d.

"THE ELECTRICIAN" WIREMAN'S POCKET BOOK. Price 5s. nett.

"THE ELECTRICIAN" HANDY WIRE TABLES FOR THE POCKET. By P. B. Down, Wh.Ex., A.M.I.Mech.E. Price 2s. 6d. nett.

THE RATING OF ELECTRIC LIGHTING, ELECTRIC TRAMWAY, AND SIMILAR UNDERTAKINGS. By W. C. Bond, M.I.E.E. Price 2s. 6d. nett.

DRUM ARMATURE WINDING AND COMMUTATORS. By F. M. Weymouth. 7s. 6d.

PRIMARY BATTERIES: THEIR CONSTRUCTION AND MANUFACTURE. By W. R. Cooper. Price 10s. 6d. nett.

SECONDARY BATTERIES: THEIR CONSTRUCTION AND MANUFACTURE. By E. J. Wade.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. Price 1s. 6d. [Price 10s. 6d. nett.

THE LOCALISATION OF FAULTS IN ELECTRIC LIGHT CABLES. By F. C. Raphael. 7s. 6d.

THE STEAM-ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. Beaumont, M.I.C.E., M.I.M E., &c. Price 6s. nett.

THE ELECTRIC ARC. By Mrs. Avrton. M.I.E.E. Price 12s. 6d.

TRAMWAY TRACTIVE EFFORT AND POWER DIAGRAM. By Arnold G. Hansard, B.A., A.M.I.E.E. Price 4s. 6d. nett; in Tube, 5s.

THE BRITISH POST OFFICE TELEPHONE SERVICE. Fully illustrated. Price 3s. 6d. nett.

INTERNATIONAL TELEGRAPH CONVENTION AND SERVICE REGULATIONS. Price 6s. nett. (LISBON REVISION, 1908.)

BOILER FEED WATER. By F. W. Anderson. Price 6s. nett.

(PRELIMINARY) WIRELESS TELEGRAPH CONFERENCE (BERLIN, 1903), PROCEEDINGS AT. Price 8s. 6d. nett.

INTERNATIONAL WIRELESS TELEGRAPH CONVENTION AND SERVICE REGULATIONS (BERLIN, 1906). With complete report of Proceedings. Price 21s. nett.

THE TWO-TONE VIBRATING TRANSMITTER AND CABLE INDUCTIVE SIGNALLING. By Edward Raymond-Barker. Price 1s. nett and post free. [Price 3s. nett.

THE CLASSIFICATION OF ALTERNATE-CURRENT MOTORS. By V. A. A. Fynn, M.I.E.E.

ELECTRIC CRANES: THEIR DESIGN, CONSTRUCTION AND APPLICATION. By H. H. Broughton. Being Vol. I. of a Complete Manual of Lifting and Hauling Machinery. *Now Ready*, price 25s. nett.

AMATEUR WIRELESS TELEGRAPH DESIGNS. By "Alfrec." Very fully illustrated. *Now Ready.* Price 1s. 6d. nett.

AITKEN'S MANUAL OF THE TELEPHONE. By W. Aitken, M.I.E.E. *Ready in October.*

ELECTRIC MAINS AND DISTRIBUTING SYSTEMS. By J. R. Dick, B.Sc., and F. Fernie, A.M.Inst.C.E. *Ready in October.*

WIREMAN'S POCKET BOOK AND ELECTRICAL CONTRACTOR'S HANDBOOK. Compiled by A. W. Robinson and W. E. Warrilow. Price 5s. nett. *Ready in October.*

ELECTRICAL MANUAL FOR MINING ENGINEERS. By H. J. S. Heather, M.I.E.E. *Ready in December.* [*In Preparation.*

THE MECHANICAL DESIGN AND CONSTRUCTION OF GENERATORS. By R. Livingstone.

STUDIES IN LIGHT PRODUCTION. By R. A. Houston, M.A., Ph.D., D.Sc. *In Preparation.*

LIGHT, RADIATION AND ILLUMINATION. From the German of Paul Hogner, by Justus Eck. *In Preparation.*

The Electrician.

The Oldest Electrical Journal (established as a weekly Journal, 1861-1879).

Published every Friday, Price Sixpence; Post Free, Sixpence-Halfpenny.

Editorial, Publishing and Printing Offices,

"THE ELECTRICIAN" INDUSTRIAL SUPPLEMENT.

With "THE ELECTRICIAN" for Sept. 14, 1906, was issued the first of a series of "Industrial Supplements," to be published from time to time with "THE ELECTRICIAN." The fifty-third issue of the Supplement published (Gratis) with the number of "THE ELECTRICIAN" for September 23, 1910, was the last of the monthly issues. "THE COMMERCIAL AND INDUSTRIAL SUPPLEMENT" to "THE ELECTRICIAN" is now issued weekly (Gratis). It will be found towards the end of the present issue.

SPECIAL NOTICE

The present number of "THE ELECTRICIAN" completes Vol. LXVII. The Index to the Volume will be issued (Gratis) on October 20th.

NEARLY READY.

Vol. LXVII. of "THE ELECTRICIAN." Bound in Publisher's covers. Price 17s. 6d. Postage U.K. 1s. extra, abroad 2s. 6d.

Cases for binding Vol. LXVII. now ready, price 2s.; post free, 2s. 3d.

CAR METERS.

Central station engineers on the introduction of the metal filament lamp consoled themselves with the prospect of obtaining additional consumers by means of its economy compared with the lamps previously in use. Experience has shown that in this they were not disappointed. The reduction in energy consumption brought about by the recent extensive adoption of car-meters by tramway undertakings does not offer, however, any compensating prospect of increased business for the supply authority. Indeed, it is possible in some cases that a worse load-factor may have to be faced as well as a smaller output. Where a flat rate of charging for energy is in force, the changed state of affairs may necessitate a reconsideration of the method of charging. In this connection, attention may be called to the Report, which will be found set out elsewhere in this issue, by a Joint Committee of the Municipal Electrical Association and the Municipal Tramways Association.

That the installation of meters on the cars has a beneficial effect in reducing the energy consumption, by making the motorman more careful in handling his controller and brakes, has now been decisively proved, although a few tramway managers, among whom is Mr. J. B. HAMILTON, may possibly dispute that the advantages thereby obtained

Digitized by Google

are material. Recent discussions have, in fact, centred more round what is the most satisfactory type of car-meter to adopt than on whether any advantage is obtained by using meters. Ampere-hour and time meters have each their advocates, whilst watt-hour meters have of recent years gone out of favour, largely owing to troubles with the pressure coils. Although the main features and advantages of each type of meter have been discussed on numerous occasions, the Paper presented by Messrs. R. G. and J. G. CUNLIFFE at the Annual Conference of the Municipal Tramways Association last week is by far the most careful examination of the subject that has been published. The electric tramway industry is already indebted to the above members of the staff of the Manchester Corporation Tramways for several important contributions to the technical side of tramway operation, and the present Paper is likely to remain a standard of reference for some time to come.

As will be seen from our abstract of Messrs. CUNLIFFE'S Paper elsewhere in the present issue, the subject is more complicated than appears at the outset, and apart from errors depending on the type of meter employed, the variation in voltage of the overhead line and local conditions prevent reliable comparisons being made between the energy consumption of cars on different routes, or even sections of the same route. This last feature is clearly shown by the readings taken on the Palatine route in Manchester. In the centre of the city where, as the authors remark, motormen have their attention fully taken up in getting their cars through the traffic, the energy consumption averages 2·26 units per car-mile, the motors being run on the series notches of the controller. On passing into less crowded thoroughfares the energy required decreases to 1·99 units per car-mile, the running being mixed series and parallel; whilst on the suburban part of the route only 1·395 units per mile are taken, the motors running in parallel for considerable periods. The average speeds at which the above sections of the route are traversed are 5·39, 8·52 and 10·9 miles per hour respectively, whilst the periods during which current is taken from the overhead line are 5·28, 3·35 and 2·99 minutes respectively per mile traversed. The above figures repay careful study, since they embody the characteristics of each type of running. Another feature which must not be lost sight of in making comparisons, is that the necessity of maintaining schedule time may prevent, on some routes, the motormen from economising current as they would under other circumstances.

One of the most valuable parts of the Paper describes the investigation of the accuracy of various meters under working conditions. In this connection the liability to considerable error in watt-meter readings on varying pressure and current will probably come as a surprise to many engineers; whilst the ampere-hour meter is found to measure the two components—current and time—with great accuracy. In order, however, to obtain reliable information from its readings, since the authors show that an exact determination of the power consumption is desirable, it is necessary to ascertain the average pressure during the period in question. For this purpose the authors have introduced a volt-hour meter (which was described in our columns last week). This instrument should also prove of considerable utility to other than tramway engineers. If it were necessary to instal this instrument on every car, in addition to another meter, we think that the additional cost and complication would prevent its general adoption; but it should be possible to obtain sufficient information as to the pressure from readings taken at the end of each journey, from a single car fitted with a volt-hour meter on each route. It has, we think, generally been admitted that the time meter is not in itself a sufficient check on the motormen, but its readings in combination with those of energy meters are of much interest. Though these readings may be very misleading as regards the relative power consumption, there is no doubt that where time meters have been installed considerable benefit has resulted, for the fact that the motormen are aware that some record is being obtained of their operations is sufficient to bring about more careful running of the cars. The extra regard thereby paid to the condition of the brakes is a case in point. We regret that Messrs. CUNLIFFE have apparently confined their attention to energy consumption, and that particulars have not been given as to the effect on various parts of the car equipment of installing meters. Thus, it would be interesting to know whether controller repairs are increased where time meters are employed, owing to the tendency of these meters to encourage too rapid handling of the controller.

An inspection of the annual reports of tramway managers issued during the past few months shows the widespread satisfaction at the results of using meters, as typical of which we may draw attention to the remarks of Mr. A. BAKER, general manager of the Birmingham Corporation Tramways, at the meeting last week. On his tramway system, with 300 meters in use, a saving in current equivalent to £5,000 has been made in nine months, in spite of an increase of a quarter of a million car-miles. Such experience is sufficient argument for the use of meters even where a tramway department possesses its own generating station, although, of course, the fact that any diminution in output increases the capital charges and wages per unit reduces the advantage in the latter case. This consideration is certainly an argument in favour of a combined station, so that the whole of the plant may be utilised to the best advantage.

OBITUARY.

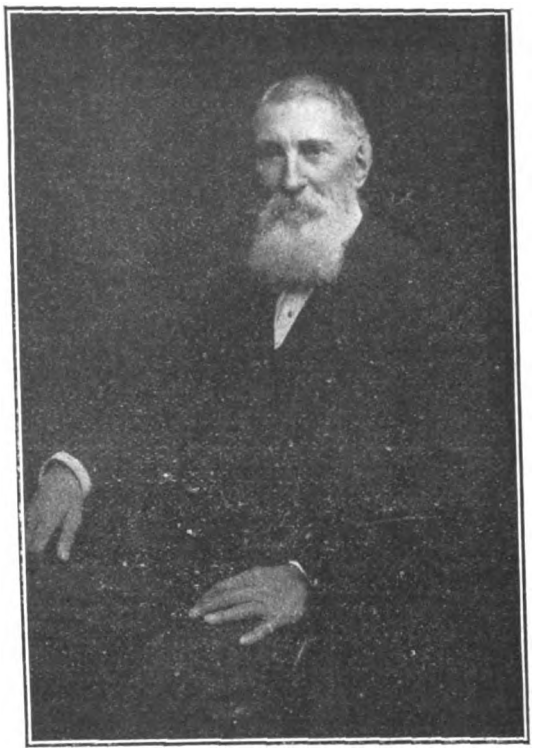
WILLIAM SHUTER.

We regret to announce the death of Mr. William Shuter, which occurred at his residence, 22, Belsize-grove, London, N.W., on October 3rd. Mr. Shuter, whose name was for so many years associated with the Telegraph Construction & Maintenance Co., was born on September 11, 1829. He commenced business life as an accountant with the firm of Deloittes, leaving them in 1856 to join Messrs. Glass, Elliot & Co., who had just taken over the business of W. Kuper & Co., wire rope makers, and were about to embark in the enterprise of making submarine telegraph cables. In 1864 Messrs. Glass, Elliot & Co., who had so far shared with Messrs. Newall almost all the contracts for telegraph cables constructed up to that time, amalgamated with the Gutta Percha Co. of

Digitized by Google

City-road, London, under the title of the Telegraph Construction & Maintenance Co., and Mr. Shuter was its first secretary. In 1882 he was appointed manager, and in 1894 managing director. On the death of Sir Robert Herbert in 1905, Mr. Shuter was elected chairman of the Company, which office he held until he resigned in 1909.

This Company has, during the 45 years that Mr. Shuter was associated with it, been engaged in the construction and submergence of more than two-thirds of all the telegraph cables in the world; he was in this way connected with the progress of submarine telegraphy from its inception; he saw many great contracts carried out successfully, including the one for the Imperial Pacific Cable, and when, in 1909, he terminated his long and valued services to the Company it was with the general regret of his colleagues, the staff, and all who came



WILLIAM SHUTER, BORN SEPT. 11, 1829—DIED OCT. 3, 1911.

into personal contact with him, to whom he endeared himself by his kindly manner and amiable nature. He was a strong personality, a shrewd man of business, and, like most successful men, a decided optimist—never afraid of taking risks or of accepting responsibility; and it is largely due to his wise financial guidance in years gone by that the Telegraph Construction & Maintenance Co. is the powerful corporation which it is to-day.

Mr. Shuter's funeral takes place to-day, Friday, at 12:30 p.m. at the Parish Church of St. John, Hampstead.

REVIEWS.

Manuale del Ingegnere Elettricista. By A. MARRO. 2nd edition. (Milan, 1911: Ulrico Hoepli.) Pp. xxv. + 862.

To most engineers, in spite of memory training systems, a good pocket-book is indispensable. The data and formulæ contained in it should be conveniently arranged, concise, and, above all things, reliable. It should not aim at supplanting the student's text-books or the specialist's treatises, but it should afford such information to the operating or constructing engineer as to enable him to use his practical knowledge quickly and efficiently, and without the brain-fag of memorising lists of formulæ. The present little work very fairly fulfils these conditions. In the first place its size is convenient—reasonably a pocket-book—yet its scope is wide, and its information exact and up to date. A good beginning is made in the three opening chapters, which give the fundamental principles of electrostatics, magnetism and the electric circuit. With the increasing development of extra-high-tension transmission frequent reference has to be made to electrostatic principles, and in this section the reader will find what he requires, with just sufficient explanation to render the formulæ intelligible. In fact, this attribute is characteristic of every section in the book.

Chapter IV. deals with instruments for and methods of measuring current, E.M.F., resistance, capacity, inductance and power, with the addition of useful notes on magnetic and photometric tests.

The next three chapters provide extensive data on central station plant: dynamos, alternators, prime-movers, transformers and converters. The notes on relative efficiencies, and the other factors that determine the choice of prime-mover, are all based on the most modern practice, as instanced by the figures given for Diesel engines.

Consuming devices—motors, incandescent and arc lamps—occupy the next two chapters. The summary of the theory of A.C. motors, including Heyland's diagram, is clear and helpful.

Chapters X. and XI. are devoted to systems of distribution which are treated with exceptional fulness and accuracy for a book of this kind. The comparative figures of merit for iron, aluminium and copper as conductors, are given, as also the simpler formulæ and methods of calculating cables and networks.

The installation of aerial lines, underground cables, batteries, transformers, motors and lamps is discussed in the next two chapters. The calculation of tramway systems has a chapter to itself, while the remainder of the book is nearly all taken up by a reprint of the regulations of the Verband Deutscher Elektrotechniker, and extracts from the Italian laws relating to electrical installations. In the final chapter some of the more recent applications of electricity are briefly described, such as copper and silver refining, the production of ozone, carbide of calcium, carborundum, with notes on the power taken by cooking appliances and machine tools. The mathematical tables, including logarithms, squares and cubes, standard differentials and integrals, form a useful appendix.

The book is essentially one for the engineer dealing with heavy work. No reference is made to telegraphic or telephonic instruments, and little or no data are given on house-wiring or the lighter accessories, such as switches and fuses. To the Italian engineer of experience, unable to consult his office records, this little book would be a helpful guide; to the average British engineer, the language and the metric system would probably prove insuperable barriers. J. R. D.

Enclycopédie Electrotechnique. Vol. V. INDUCTION ET COURANTS ALTERNATIFS. By EUGENE VIGNERON. (Paris, 1910: L. Geisler.) Pp. 147.

This book, which forms the fifth volume of an Electrotechnical Encyclopædia, though hardly corresponding with our English ideas of an alphabetically arranged series, is another example of the remarkably erudite and elegant theoretical treatises with which French engineers frequently present us and which one would hardly have expected from practical men. The author makes an attempt to develop in a clear and logical form, the theory of induction and of alternating currents starting from the experimental basis of Faraday's discoveries. While, however, the mathematical reasoning is brief and clear if somewhat academic, we confess to some difficulties over the logic or basis of the theory. After mentioning that the theory of induction must have an experimental basis, and stating that this is afforded by the experiments of Faraday, the author proceeds to mention some experiments which are practically similar, and then builds up the general expression for the current as depending upon the difference between the impressed E.M.F. and the time rate of change of the flux. But we are then told that Faraday's discovery was simply that this formula holds good even when the impressed E.M.F. is zero, and that there is therefore no discontinuity in the formula. Surely it would be more correct to say that the whole basis of the theory of induction lies in Faraday's experiments, and that the complete formula is a generalisation from them by logical reasoning, and which is found to be in conformity with experiment.

Digitized by Google

in all cases. We are sorry also to see that the author constantly speaks of extra *currents* instead of induced E.M.F.

One other point which seems open to criticism is the treatment of certain discharge problems by energy principles. It is certainly true that the mathematical working is thereby greatly simplified, and that correct results are obtained in the special case selected; but there is just the same fundamental error as in attempting to solve dynamic problems on the basis of energy rather than momentum, and the student might be led to apply these methods in absolutely unsuitable cases.

But, apart from these somewhat debatable points, we can cordially recommend this book as presenting its subject in as simple and clear a manner as orthodox mathematical methods will permit. One of the best features is the extremely neat and simple proof of Neumann's mutual induction formula from elementary principles, a clear understanding of which is much needed, even by the majority of mathematical physicists.

The alternate-current section does not call for much comment, except to mention that it puts the ordinary theory clearly and concisely, that the vector diagrams are good and well explained, and the vector theory of Steinmetz well developed. C. V. D.

Electric Wiring, Fittings, Switches and Lamps. By W. Perren Maycock. 4th edition. (London, 1911 : Whittaker & Co.) Pp. x. + 628. 6s. net.

This comprehensive work has been brought up to date in this—the fourth—edition. The author has in some measure defeated his object by attempting too much. We ventured upon this criticism in our review of the previous edition, and the present volume confirms the opinion which we then expressed—namely, that there are sections of the book which might with advantage be developed as separate volumes. However, the author has adhered to his original plan of crowding the largest possible amount of information within the compass of a single volume, which numbers over 600 pages. The book is mainly divided into sections, which deal with wiring and wiring methods, circuit accessories of every description, illuminating units, electric signs and electric heating, small motors, bells, telephones, fire-alarms and clocks. As a complete repository on the subject of wiring from the main terminals to the electricity consuming devices the book has everything to commend it. As a publication of this nature it lays itself open to criticism, being of the catalogue order. The book is intended to serve as a wiring text book for students, but we cannot help thinking that the multiplicity of subjects dealt with by the author in his efforts to produce a comprehensive work will lead to some confusion. This particularly applies to the great variety of wiring diagrams. In practice so few of these are required that the wireman seeks the information which he needs at the moment from the pages of a switchmaker's catalogue.

We think the scheme of indexing the numbered paragraphs in the book is clumsy and misleading. It would have been far more convenient to index the items by the pages on which they appear.

Compulsory Working of Letters Patent. By F. W. Beney. (London : W. Clowes & Sons.) pp. 15. 3d.

Much has been written on the effect of sec. 27 of the Patents and Designs Act, 1907, which is commonly known as the compulsory working clause, but few writers have studied the question from the imperial point of view, and therefore we are glad to see that Mr. F. W. Beney, who has made a special investigation into the subject of the feasibility of unifying the patent law and practice of the different parts of the Empire, has published a general review of the situation as it presents itself to him after three years' working of the Act. In the "Empire Review" for January the author pointed out the difficulties to be overcome before uniformity could be attained throughout the Empire. The subject is, indeed, an important one from the industrial and economic points of view. It came before the recent Imperial Conference at one of its sittings, but nothing tangible was done, though there was general agreement as to the need for uniformity in the patent laws of the various parts of the Empire. In his interesting pamphlet on "The Compulsory Working of Letters Patent in its Imperial and Economic Aspects" Mr. Beney pleads for the abolition of the working conditions in the case of patents granted to imperial citizens, and for the exoneration of foreign patentees from the obligations of sec. 27 where they reside in a State that is willing to grant us reciprocal advantages. Like ourselves, the author thinks the form of sec. 27 too drastic; it is useful for certain purposes, but when applied universally it has serious disadvantages. We do not intend again to detail these drawbacks, but we recommend those of our readers who are interested in this question to read Mr. Beney's pamphlet, which is clearly and cogently written.

TENTH ANNUAL CONFERENCE OF THE MUNICIPAL TRAMWAYS ASSOCIATION.

The Municipal Tramways Association held their annual conference last week at Glasgow, under the presidency of Mr. J. Dalrymple, general manager of the Glasgow Corporation tramways. The proceedings opened on Wednesday (September 27th) in the Council Hall of the Glasgow City Chambers. The Lord Provost (Sir Archibald McInnes Shaw, LL.D.) welcomed some 180 members of the Association to Glasgow in his usual racy, military style, and dwelt upon the mutual support such an Association could give to individual members, tending to develop, as it did, the exchange of ideas and the further improvement of electric traction for the common weal. He instanced Glasgow as having probably the cheapest tramway fares in the world; but some of the community still wanted a further reduction. The 1½d. two-stage fare had, he considered, been a huge success. Bailie Russell (Glasgow) also spoke, and said the Association had justified its existence.

Mr. Blain (West Ham), on behalf of the Association, thanked the Corporation of Glasgow for their welcome. Glasgow was, he said, considered the Mecca of all tramway experts, on account of the ideal manner in which the system was there organised and conducted.

Mr. Dalrymple then took the chair and delivered his presidential address, of which the following is a brief abstract:—

PRESIDENTIAL ADDRESS.

In his address Mr. Dalrymple said that, although their Association was one of the youngest and smallest connected with municipal work, it was among the most vigorous. He thought it a pity that the tramwaymen of this country should be divided into two camps; and it looked as if the two Associations were to drift further apart, seeing that the Municipal Tramways Association had just got their charter of incorporation. He hoped, however, it would be possible for the two Associations to work together.

In regard to the Papers that had from time to time been read and discussed, he was anxious that members should take up what might be called the small change of tramway management. Thus "track construction and maintenance" was too comprehensive a subject for one Paper. The track might be subdivided into 10 or 12 sections, each of which provided sufficient material for a Paper and discussion. Similarly with rolling stock. His object was to put in a strong plea for careful detail work.

At the present time they were watching very carefully the operation of rail-less cars in Leeds and Bradford, and developments in America in connection with storage batteries. Nearly all the large American street railway companies were collecting the fares of passengers on the platform before they entered the car.

The President next referred to the changes in Glasgow rolling stock of recent years, and finally mentioned what was being done as regards investigating the cause of rail corrugation and a basis for fixing the charge for current supplied to tramway departments.

Mr. C. J. Spencer (Bradford) moved a vote of thanks to Mr. Dalrymple, who, in replying, said the Executive of the Association were at present negotiating with the Board of Trade for small tramway systems to obtain powers at a reasonable cost to run trackless trolley cars.

Councillor W. Nelson (sub-convenor of the Glasgow Cor-

Digitized by Google

poration tramways) then read a Paper (of which the following is a summary), entitled :—

"The Common Good of the City of Glasgow, its Origin, History and Present Position in Relation to the Tramways Undertaking."

The "common good" originally commenced with the common lands belonging to the community, and has developed until the total revenue from all sources last year amounted to some £175,000; whilst the expenditure, including over £6,619 donations to charities, was £119,000. To this revenue the tramways, which by a recent Act of Parliament are deemed to have always been part of the Common Good, contributed last year £68,678. Part of the balance in 1910 was used to reduce the parks rate—a rate falling wholly upon occupiers—by 2d. in the £1. This year the balance is to go to a suspense account for the removal of undesirable property in congested districts within the city.

At the conclusion of the Paper the author was asked a number of questions, and in replying Councillor Nelson said that, apart from the trams, the Common Good Fund was substantial, and on its security they had borrowed some £2,000,000 for tramway purposes. Undoubtedly, considerable inroads had been made on the funds in former times, but he thought a more enlightened policy would give even greater benefit to the community.

Members then adjourned for lunch, which was provided by the Corporation of Glasgow (out of the Common Good Fund, by the way). On resuming, Councillor J. H. Rodgers (chairman of the Newcastle-on-Tyne Tramways Committee) presented a Paper, of which the following is a summary, on

"Tramways Finances and Policy."

The author surveys the policy of many municipally owned tramway systems. His ideas are: (1) A system should be made financially sound by ample reserve funds; (2) proper travelling accommodation and service should be made for the public; (3) sufficient and adequate conditions of service for the employés should be provided; (4) there should be some recompense to the ratepayers who footed the bill by an adequate contribution to the relief of the rates.

No fewer than 28 out of 88 municipal tramway systems referred to by the author had no reserve fund. Many gave a contribution to the relief of rates with considerable *éclat*, but, in his opinion, on an unsound basis, as they robbed their renewals funds. No fewer than 34 systems made a loss last year, and he feared this number would increase if Committees knuckled under to the agitation for further concessions to ratepayers and employés.

In only 10 places where ½d. fares were in force was the system successful; and four of these systems (including Glasgow) were in Scotland. But Glasgow had one million inhabitants, who were carried on the average over 200 times per annum, as against a town of which he knew with 30,000 to 40,000 inhabitants, who were only carried on the average 40 or 50 times per annum. Glasgow had a relatively dense population, whilst the other town was sparsely populated and very scattered, a point usually ignored.

He was also against cheap fares at certain hours of the morning and evening.

The recent tramway employés strikes were, he considered, due to a misconception on the part of the men—that the trams were a co-partnership concern, more for their own betterment, and not the communal benefit. He thought that, as a class, the tramway employé was considerately dealt with, and had no long term of apprenticeship to serve; and he deprecated the cheap notoriety gained by some committeemen who were for granting undue concessions, not only to the employés but to the public clamouring for extended ½d. and workmen's fares and other quagmires leading to disastrous financial results.

The greater part of the afternoon was taken up in discussing this Paper. In the evening, the Corporation (again out of the Common Good Fund) entertained the members to dinner, the Lord Provost being in the chair. Among the speakers were Sir John Ure Primrose, Bart., Mr. Whitaker Thomson (London County Council), Bailie Russell, Mr. Niessen (Amsterdam), and Alderman Bowes (Manchester).

Thursday, September 28th.

To-day's meetings took place in the men's hall at Newland's depot. Messrs. R. G. Cunliffe and J. G. Cunliffe read a Paper* on "Tramcar Meters."

Mr. T. B. Goodyer (Croydon), in opening the discussion, confessed to being a very strong advocate of the use of meters. He instanced Berlin's saving of £21,000 per annum, and said that the adoption of meters on the Cape Town cars had also proved a financial success.

Mr. W. Clough (Bury) said his concern was what type of meter to adopt. The ampere-hour meter neglected the voltage, and he could not accept it as being the scientific solution. He would agree to accept the watt-hour type as satisfying all the conditions, and he knew of such types proving quite satisfactory. He had had 50 in use on his system for the past 18 months at maker's risk. They were under a guarantee of keeping accurate within 3 per cent., and complete maintenance was provided for 6s. per meter per annum. He expressed surprise at the results given in the Paper. While 1 per cent. accuracy was quite good for laboratory tests, still, taken in conjunction with the running conditions, he thought the percentage error would be increased to 3 per cent. He considered the authors were not quite consistent, for first they advocated accurate values and later advocated average values. Average values would not suit him. With regard to the influence on the motorman, he found in Bury that the introduction of meters led to great improvement, not only in the saving of current, but by a more regular spacing of the cars along the routes. This latter effect probably meant that less time was being lost at the various termini. The approximate saving to Bury was £2,000 per annum.

Mr. R. S. Pilcher (Aberdeen) referred to his Paper* read in London two years ago. Rapid progress had been made since then, and he was of opinion that the use of meters was becoming universal. He found his saving during the last three years to be 13 per cent. It was important to warn motormen not to get on to parallel running until they saw a clear roadway ahead. He frequently found the tendency was to get over the series notches as fast as possible in accelerating speed. He also advocated the grouping of men to cars.

Mr. A. Baker (Birmingham) confessed to looking upon meters now as a necessary part of a car's equipment. Last year they had installed 300 meters, and the saving in nine months was some £5,000, even with an increase of 250,000 car-miles. The use of meters had also reduced the consumption of brake shoes by 30 per cent. It further raised the standard of efficiency among the men by forming an incentive in the way of friendly rivalry. Any increase in the number of accidents was probably due to sudden starting and stopping, with the object of accelerating as quickly as possible.

Mr. J. B. Hamilton (Leeds) said he was no ardent supporter of meters. Probably their use was advocated more by tramway departments not generating their own current; but for those with their own power stations he could not see what improvement it could possibly make. The mania for "reduction of current" was, he thought, being overdone. The use of meters reminded him of the story of the Irishman who found his blanket did not cover his feet, so he cut a bit off from the end near his head to sew on to the foot.

Mr. C. J. Spencer (Bradford) thought that Mr. Hamilton's objections to meters were probably due to inexperience. He thought Bradford was the first town to adopt them. Whilst there were undoubted differences in types, there were other more important differences. He was no advocate of the grouping of men to any particular car, as advocated by Mr. Pilcher. Apart from the clerical work involved——

Mr. Pilcher here said that there was no additional clerical work. The men took their own readings.

Mr. Spencer, continuing: There was the difference in the men themselves. When meters were first used he found even 30 per cent. difference between the best and worst drivers, but now the difference had been reduced to 5 per cent.

Mr. Dalrymple asked whether the worst men improved that much.

Mr. Spencer replied that some did and others left.

Mr. A. Ellis (Cardiff) said his department not only generated the power current but sold it to the lighting department. The works cost to the trams was 0·4d. per unit. They had 130 meters in use, and thought they could still reduce the current consumption with benefit. He tried the system of adjustment of wages on current consumed, and made it subject to revision every six months. He could not agree to grouping, as in Aberdeen. His men checked their own readings. His meters had been in use some six months.

Mr. R. G. Cunliffe, in reply, said he was glad to hear of so many in agreement as to the use of meters. Their adoption showed up the faults of a car very much sooner than where they were not used. Cars with faulty coils were very quickly indicated, thus reducing maintenance costs. The average values referred to were only for use as relative values to show the differences between careful and careless men. The maximum period taken for this purpose was one month. His reason for advocating ampere-hour meters was due to the absence of the very fine wire in the pressure coil. In the ampere-hour meter there was no such coil, with its frequent breakdown. Besides that, it was a stronger instrument and much simpler for the average man to connect up. Traffic conditions did not make a very material difference. In Manchester it was found 0·5 unit per car-mile.

Mr. Hamilton wished to deny Mr. Spencer's insinuation regarding lack of experience. As a matter of fact, he had several meters in use experimentally, but this did not alter the opinion expressed.

After Mr. Dalrymple had moved a vote of thanks to Messrs. Cunliffe, Messrs. J. Grierson (Glasgow), H. Mattinson (Manchester) and R. B. Holt (Leeds) presented reports on "Tramway Track: Methods of Construction and Maintenance."

These reports were based on tabulated replies to queries in

* An abstract of this Paper is given on p. 997 of this issue.

* *See* The Electrician, September 24, 1909, p. 952.

Digitized by Google

respect to present practice in permanent way work. As the authors had found it impossible to come to a unanimous agreement for a first report, they had agreed to draw up individual reports. (We regret that owing to pressure on our space it has been necessary to hold over our abstract of these reports until next week.—ED. *E.*)

Mr. H. MOZLEY (Burnley), in opening the discussion, gave a long dissertation on the history of rail welding, and was frequently interrupted.

Mr. J. M. MCELROY (Manchester) said the silicon rail showed an increase in life of 33⅓ per cent. He was surprised the experience at Glasgow should have been contrary to that at Manchester. In Manchester there were some 7,000 welded joints, and cracks or breakages only amounted to 0·3 per cent., not 3 per cent., as printed in the report. The whole matter depended on the weld, whether made by experienced men or inexperienced labour. If by the latter, nothing but disappointment could be expected. His three years' experience convinced him that the thermit weld could not be improved upon, provided it was made by the Thermit Co.'s experienced men. This was the course he adopted, and a bonus was further given for every joint which did not break.

Mr. R. L. ACLAND (Chesterfield) thought that the best way of arriving at a conclusion was to appoint a commission of enquiry, and he submitted one or two subjects which might be considered by such a commission: (1) Section and composition of the rails, with a standard specification; (2) foundations; (3) a standard joint; (4) use of anchors; (5) to report fully on the question of manganese. He pleaded strongly for standardisation. Large Corporations could afford to do as they were doing at present, but the smaller concerns could not afford to experiment.

Mr. J. F. SIMPSON (Preston) also asked for more information. It was agreed that the Executive Committee should decide what action to take.

Mr. KNOWLES (Sheffield) said it would be interesting to more than himself to learn what kind of steel was used at Glasgow.

Mr. DALRYMPLE, in reply, said it was open hearth steel, a kind which the Thermit Co. would not undertake to make joints on.

Members then adjourned for lunch, again provided by the Corporation out of the Common Good Fund. Thereafter a photograph of the company was taken and the annual business meeting was held. Mr. H. E. Blain, of West Ham, was unanimously elected president of the Association for the ensuing year, and it was decided to hold next year's Conference at West Ham.

The other office-bearers elected were:—*vice-president*, Mr. A. R. Fearnley (Sheffield); *hon. secretary and treasurer*, Mr. C. J. Spencer (Bradford); *members of council*, Alderman White (West Ham) *ex-officio*, Alderman Flint (Leicester), Alderman Rodgers (Newcastle-on-Tyne), Messrs. T. B. Goodyer (Croydon), J. B. Hamilton (Leeds), W. Clough (Bury), P. Fisher (Dundee), and J. Aldworth (Nottingham.)

Alderman Hunt (Birmingham), in proposing a vote of thanks to the Lord Provost and Glasgow Corporation Tramways Committee for the hospitality extended to the Association, said that he had been on many deputations, but they had never been entertained in the princely fashion that the Association had been in Glasgow.

A hearty vote of thanks was also accorded Mr. Dalrymple for his services as president.

A trip was then made to Rouken Glen on reserved cars, the day's proceedings finishing up with the Annual Association dinner in the Grosvenor Restaurant. At this dinner a large company of ladies and gentlemen were present. Mr. J. Dalrymple occupied the chair, whilst the Lord Provost and Lady McInnes Shaw were amongst the guests. The main toast, that of "The City and Corporation of Glasgow," was proposed by Mr. H. E. Blain and acknowledged by the Lord Provost.

Friday, September 29th.

To-day was spent in an excursion to the Burns country round about Ayr, on the invitation of the Ayr Corporation. Good weather prevailed, and altogether the Conference was an undoubted success.

An interesting feature, in the form of a side show, at the Newland's depot was the specially arranged exhibition of tramway material, from the latest type of covered top deck, 7 ft. wheel base, end-screened Glasgow car to the latest idea in overhead trolley wire insulation. Many well-known firms exhibited material, including car trucks, controllers, trolley arms, rail sections, rail cross-overs and junctions, speed indicators, brakes, signs, &c.

THE SINGLE-PHASE REPULSION MOTOR.*

BY THOMAS F. WALL, M.SC., M.ENG.

(*Continued from page* 980.)

Summary.—In the first part of this Paper expressions are deduced for the E.M.F.s induced in the stator and rotor windings, and curves are given which enable some of these E.M.F.s to be rapidly determined for any value of the displacement of the rotor brushes from the stator axis. In the second part of the Paper the results previously obtained are employed in developing the theory of the repulsion motor. A series of simultaneous equations enable expressions to be obtained for the speed, stator current, power factor and power of the motor. In the third part of the Paper the results of some tests on a 6 B.H.P. motor are given, and the values of the stator current, power factor and speed are shown to be in agreement with the theory. Finally, a method of calculating the open circuit characteristic of a single-phase motor is given.

We shall now consider the general case in which the resistances and leakage inductances of the stator and rotor windings respectively, are taken into account.

Let r_1 be the resistance of the stator winding.
Let r_2 be the resistance of the rotor winding.
Let S_1 be the leakage inductance of the stator winding (in henries).
Let S_2 be the leakage inductance of the rotor winding (in henries).
Let the pressure applied to the stator terminals be a sine function of the time and represented at any time t by

$$p = -P \sin 2\pi\nu t.$$

Then the following equations must hold:—

$$-\frac{dL_s}{dt}10^{-8} - r_1 i_1 - S_1 \frac{di_1}{dt} + p = 0, \quad . \quad . \quad . \quad . \quad . \quad (24)$$

$$L_s = L_{s\max.} \cos(2\pi\nu t + \beta_s), \quad . \quad . \quad . \quad . \quad . \quad . \quad (25)$$

$$L_s = A_1 D_1 i_1 + A_2 D_2 i_2, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (26)$$

$$L_R = A_1 C_1 i_1 + A_2 C_2 i_2, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (27)$$

$$EA_1 i_1 n - S_2 \frac{di_2}{dt} - r_2 i_2 - \frac{dL_m}{dt}10^{-8} = 0. \quad . \quad . \quad . \quad (28)$$

$(90-\beta_s)$ is the angle of displacement of the stator flux linkages relatively to the applied pressure at the stator terminals. Suppose at the time $t=t_1$, i_1 passes through its zero value in a direction from positive to negative. Then at the time $t=t_1-\frac{1}{4\nu}$, i_1 attains its maximum value $\bar{I}_1$, and $\frac{di_1}{dt}=0$.

Therefore, from (24) and (25)

$$2\pi\nu L_{s\max.} \sin\left[2\pi\nu\left(t_1-\frac{1}{4\nu}\right)+\beta_s\right]10^{-8} - r_1\bar{I}_1 - \bar{P}\sin 2\pi\nu\left(t_1-\frac{1}{4\nu}\right)=0.$$

or $$-2\pi\nu L_{s\max.}\cos(2\pi\nu t_1+\beta_s)10^{-8} - r_1\bar{I}_1 + \bar{P}\cos 2\pi\nu t_1 = 0, \quad ; \quad (29)$$

$$L_{s\max.}\cos\left[2\pi\nu\left(t_1-\frac{1}{4\nu}\right)+\beta_s\right] = A_1D_1\bar{I}_1 + A_2D_2 i_2$$

or $$L_{s\max.}\sin(2\pi\nu t_1+\beta_s) = A_1D_1\bar{I}_1 + A_2D_2 i_2, \quad . \quad . \quad . \quad (30)$$

$$EA_1\bar{I}_1 n - S_2\frac{di_2}{dt} - r_2 i_2 - A_2C_2\frac{di_2}{dt}10^{-8} = 0. \quad . \quad . \quad . \quad (31)$$

At time $t=t_1$, $i_1=0$. Therefore,

$$2\pi\nu L_{s\max.}\sin(2\pi\nu t_1+\beta_s)10^{-8} - S_1\left[\frac{di_1}{dt}\right]_{i_1=0} - P\sin 2\pi\nu t_1 = 0. \quad (32)$$

$$L_{s\max.}\cos(2\pi\nu t_1+\beta_s) = A_2D_2 i'_2 \quad . \quad . \quad . \quad . \quad . \quad (33)$$

$$-S_2\frac{di'_2}{dt} - r_2 i'_2 - A_2C_2\frac{di'_2}{dt}10^{-8} - A_1C_1\left[\frac{di_1}{dt}\right]_{i_1=0}10^{-8} = 0. \quad . \quad . \quad (34)$$

$$\left[\frac{di_1}{dt}\right]_{i_1=0} = -2\pi\nu\bar{I}_1. \quad . \quad . \quad . \quad . \quad . \quad . \quad (35)$$

Again, from (25) and (26) we get

$$L_{s\max.}\cos(2\pi\nu t+\beta_s) = A_1D_1 i_1 + A_2D_2 i_2.$$

Differentiating with respect to t we get

$$-2\pi\nu L_{s\max.}\sin(2\pi\nu t+\beta_s) = A_1D_1\frac{di_1}{dt} + A_2D_2\frac{di_2}{dt}.$$

* Paper read before Section G of the British Association at Portsmouth

Digitized by Google

At the time $t=t_1-\frac{1}{4\nu}$, i_1 is a maximum, $\therefore \frac{di_1}{dt}=0$ and

$$-2\pi\nu L_{s\max.}\sin\left[2\pi\nu\left(t_1-\frac{1}{4\nu}\right)+\beta_s\right]=A_2D_2\frac{di_2}{dt},$$

i.e.,
$$2\pi\nu L_{s\max.}\cos(2\pi\nu t_1+\beta_s)=A_2D_2\frac{di_2}{dt}. \quad . \quad . \quad . \quad . \quad (36)$$

From (31) and (36) we get

$$EA_1I_1n-\left(\frac{S_2+A_2C_2\cdot10^{-8}}{A_2D_2}\right)2\pi\nu L_{s\max.}\cos(2\pi\nu t_1+\beta_s)-r_2i_2=0. \quad (37)$$

From (29), (30) and (37) we get:

$$0=EA_1\bar{I}_1n+\left(\frac{S_2+A_2C_2\cdot10^{-8}}{A_2D_2}\right)(r_1\bar{I}_1-P\cos2\pi\nu t_1)10^8 - r_2\left[\frac{L_{s\max.}\sin(2\pi\nu t_1+\beta_s)-A_1D_1\bar{I}_1}{A_2D_2}\right]. \quad (38)$$

From (32), (35) and (38) we get

$$0=EA_1\bar{I}_1n+\left(\frac{S_2+A_2C_2\cdot10^{-8}}{A_2D_2}\right)(r_1\bar{I}_1-P\cos2\pi\nu t_1)10^8 - \frac{r_2}{A_2D_2}\left[\frac{-S_1\cdot2\pi\nu\bar{I}_1\cdot10^8+P\sin2\pi\nu t_1\cdot10^8}{2\pi\nu}-A_1D_1\bar{I}_1\right]. \quad (39)$$

Re-writing (39) as follows:

$$EA_1\bar{I}_1n+\left(\frac{S_2+A_2C_2\cdot10^{-8}}{A_2D_2}\right)r_1\bar{I}_1\cdot10^8-\left(\frac{S_2+A_2C_2\cdot10^{-8}}{A_2D_2}\right)P\cos2\pi\nu t_1\cdot10^8 - \frac{r_2}{A_2D_2}\cdot10^8\frac{\bar{P}\sin2\pi\nu t_1}{2\pi\nu}+\frac{r_2}{A_2D_2}S_1\bar{I}_1\cdot10^8+r_2\frac{A_1D_1}{A_2D_2}\bar{I}_1=0$$

or
$$\bar{I}_1\left[EA_1n+r_1\left(\frac{S_2\cdot10^8}{A_2D_2}+\frac{C_2}{D_2}\right)+\frac{r_2S_1}{A_2D_2}\cdot10^8+r_2\frac{A_1D_1}{A_2D_2}\right] = \frac{S_2\cdot10^8+A_2C_2}{A_2D_2}P\cos2\pi\nu t_1+\frac{r_2}{A_2D_2}\frac{P\sin2\pi\nu t_1}{2\pi\nu}\cdot10^8$$

$$=P\sqrt{\left(\frac{S_2\cdot10^8+A_2C_2}{A_2D_2}\right)^2+\left(\frac{r_2\cdot10^8}{A_2D_2\cdot2\pi\nu}\right)^2}\cos(2\pi\nu t_1-a),$$

where* $\tan a=\frac{r_2\cdot10^8}{2\pi\nu(S_2\cdot10^8+A_2C_2)}$,

$$\therefore \quad \bar{I}_1=\frac{\bar{P}\sqrt{(S_2\cdot10^8+A_2C_2)^2+\left(\frac{r_2\cdot10^8}{2\pi\nu}\right)^2}\cos(2\pi\nu t_1-a)}{\left[EA_1A_2D_2n+r_1S_2\cdot10^8+r_1A_2C_2+r_2S_1\cdot10^8+r_2A_1D_1\right]}. \quad (40)$$

If we put $r_1=0$, $r_2=0$, $S_1=0$, $S_2=0$, we get $a=0$, and noting that $\bar{P}=\sqrt{2}P$

$$\bar{I}_1=\frac{PA_2C_2}{EA_1A_2D_2n}\cos2\pi\nu t_1 = \frac{\sqrt{2}PC_2}{EA_1D_2n}\cos2\pi\nu t_1,$$

which is the same as equation (22), page 980.

Again, from (25) and (26), by differentiation, we have

$$-2\pi\nu L_{s\max.}\sin(2\pi\nu t+\beta_s)=A_1D_1\frac{di_1}{dt}+A_2D_2\frac{di_2}{dt}. \quad . \quad . \quad (41)$$

From (35) and (41) we get, for time $t=t_1$,

$$-2\pi\nu L_{s\max.}\sin(2\pi\nu t_1+\beta_s)=-2\pi\nu\bar{I}_1A_1D_1+A_2D_2\frac{di'_2}{dt}. \quad (42)$$

From (34), (35) and (42)

$$-2\pi\nu L_{s\max.}\sin(2\pi\nu t_1+\beta_s)=-2\pi\nu\bar{I}_1A_1D_1 + A_2D_2\left[\frac{2\pi\nu\bar{I}_1A_1C_1\cdot10^{-8}-r_2i'_2}{S_2+A_2C_2\cdot10^{-8}}\right]. \quad (43)$$

From (33) and (43)

$$-2\pi\nu L_{s\max.}\sin(2\pi\nu t_1+\beta_s)=-2\pi\nu\bar{I}_1A_1D_1 + A_2D_2\left[\frac{2\pi\nu\bar{I}_1A_1C_1\cdot10^{-8}-r_2\frac{L_{s\max.}}{A_2D_2}\cos(2\pi\nu t_1+\beta_s)}{S_2+A_2C_2\cdot10^{-8}}\right]. \quad (44)$$

From (29) and (44)

$$-2\pi\nu L_{s\max.}\sin(2\pi\nu t_1+\beta_s)=-2\pi\nu\bar{I}_1A_1D_1 + A_2D_2\left[\frac{2\pi\nu\bar{I}_1A_1C_1\cdot10^{-8}+\frac{r_2\cdot10^8}{A_2D_2}\left(r_1\bar{I}_1-\frac{P\cos2\pi\nu t_1}{2\pi\nu}\right)}{S_2+A_2C_2\cdot10^{-8}}\right]. \quad (45)$$

* The letter a has been used in the first part of this Paper in a different sense, namely, in connection with the unwound portion of the stator.

From (32), (35) and (45)

$$[P\sin2\pi\nu t_1-2\pi\nu\bar{I}_1S_1]10^8=+2\pi\nu\bar{I}_1A_1D_1 + \frac{\left[r_2\frac{P\cos2\pi\nu t_1\cdot10^8}{2\pi\nu}-\frac{r_2r_1\bar{I}_1\cdot10^8}{2\pi\nu}-A_1C_1A_2D_2\bar{I}_1\cdot2\pi\nu\cdot10^{-8}\right]}{S_2+A_2C_2\cdot10^{-8}}. \quad (46)$$

Simplifying (46) we get

$$\bar{I}_1=\frac{P\cdot10^8\sqrt{1+\left[\frac{r_2}{2\pi\nu(S_2+A_2C_2\cdot10^{-8})}\right]^2}\sin(2\pi\nu t_1-a)}{\left\{2\pi\nu A_1D_1+2\pi\nu S_1\cdot10^8-\frac{\left[A_1A_2C_1D_2\cdot2\pi\nu\cdot10^{-8}+\frac{r_1r_2}{2\pi\nu}\cdot10^8\right]}{S_2+A_2C_2\cdot10^{-8}}\right\}}, \quad (47)$$

$$\tan a=\frac{r_2}{2\pi\nu(S_2+A_2C_2\cdot10^{-8})}$$

as before.

Equation (47) is the equation of a circle the diameter of which makes an angle $(\pi/2+a)$ with the ordinate axis—*i.e.*, the axis along which the pressure P is drawn.

Equation (47) *gives the circle diagram of the repulsion motor.*

The circle represented by equation (47) is shown in Fig. 16, in which OA is a current vector and $\phi=2\pi\nu t_1$ is the angle of lag of OA. Let CB be any line drawn at right angles to the diameter OD of the circle.

From equation (40) we have: The speed n is proportional to

$$\left[\frac{\cos(2\pi\nu t_1-a)}{\bar{I}_1}\right]-\text{a constant.}$$

But
$$\frac{\cos(2\pi\nu t_1-a)}{\bar{I}_1}=\frac{BC}{OB.OA}=\frac{BC}{OC.OD}=\frac{BC}{\text{a constant}}.$$

Therefore, the speed is proportional to CB minus some constant quantity, which constant may be represented by CE. *Hence the speed of the motor is given by the distance from a fixed point, E, of the intersection of the current vector on a line drawn perpendicular to the diameter of the current circle.*

Dividing equation (47) by equation (40) we get

$$\tan(2\pi\nu t_1-a)=\frac{2\pi\nu A_1D_1+2\pi\nu S_1\cdot10^8-\frac{A_1A_2C_1D_2\cdot2\pi\nu\cdot10^{-8}+\frac{r_1r_2}{2\pi\nu}\cdot10^8}{S_2+A_2C_2\cdot10^{-8}}}{10^8\times\left(\frac{EA_1A_2D_2n}{S_2\cdot10^8+A_2C_2}+r_1+\frac{r_2(S_1\cdot10^8+A_1D_1)}{S_2\cdot10^8+A_2C_2}\right)}. \quad (48)$$

Substituting for $\tan a$ its value as given above, we get for the angle of lag $2\pi\nu t_1$ of the current behind the applied pressure. (If Δ be used to represent the right-hand side of 48.)

$$\tan2\pi\nu t_1=\left[\frac{r_2}{2\pi\nu(S_2+A_2C_2\cdot10^{-8})}+\Delta\right]\Big/\left(1-\frac{r_2\Delta}{2\pi\nu(S_2+A_2C_2\cdot10^{-8})}\right).$$

It is to be noticed that the equations (40) and (47) give the maximum values of the current, and in order to obtain the effective values they must be divided by $\sqrt{2}$. When drawing the current circles the diameter of the circle as obtained from equation (47) should, therefore, be divided by $\sqrt{2}$.

The Representation on the Circle Diagram of the Power and Torque of the Motor.—The torque of the motor is equal to the power divided by the angular velocity.

The power of the motor will be given by the product of the R.M.S. value of the E.M.F. of rotation, the R.M.S. value of the rotor current and the cosine of the angle between them.

Let $i_2=I_2\sin2\pi\nu(t-t_2)$ be the equation for the rotor current. Then we have, as before,

For the time $t=t_1$, $i_1=0$, $\frac{di_1}{dt}=-2\pi\nu\bar{I}_1$.

Therefore from equations (25) and (26)

$$L_{s\max.}\cos(2\pi\nu t_1+\beta_s)=A_2D_2\bar{I}_2\sin2\pi\nu(t_1-t_2). \quad . \quad . \quad (49)$$

From equations (24) and (25)

$$2\pi\nu L_{s\max.}\cdot10^{-8}\sin(2\pi\nu t_1+\beta_s)+2\pi\nu\bar{I}_1S_1-\bar{P}\sin2\pi\nu t_1=0. \quad (50)$$

For the time $t=t_1-\frac{1}{4\nu}$, i_1 is a maximum and $\frac{di_1}{dt}=0$.

From equations (24) and (25)

$$2\pi\nu L_{s\max.}\cdot10^{-8}\sin(2\pi\nu t_1-\pi/2+\beta_s)-r_1\bar{I}_1-P\sin2\pi\nu\left(t_1-\frac{1}{4\nu}\right)=0.$$

i.e.,
$$-2\pi\nu L_{s\max.}\cdot10^{-8}\cos(2\pi\nu t_1+\beta_s)-r_1\bar{I}_1+\bar{P}\cos2\pi\nu t_1=0. \quad (51)$$

From equations (25) and (26)

$$L_{s\max.}\cos(2\pi\nu t_1-\pi/2+\beta_s)=A_1D_1\bar{I}_1+A_2D_2\bar{I}_2\sin2\pi\nu\left(t_1-\frac{1}{4\nu}-t_2\right).$$

i.e.,
$$L_{s\max.}\sin(2\pi\nu t_1+\beta_s)=A_1D_1\bar{I}_1-A_2D_2\bar{I}_2\cos2\pi\nu(t_1-t_2). \quad (52)$$

Digitized by Google

Therefore from (52) and (50)

$$A_2D_2\bar{I}_2\cos 2\pi\nu(t_1-t_2)=A_1D_1\bar{I}_1+\frac{(2\pi\nu_1S_1\bar{I}_1-\bar{P}\sin 2\pi\nu t_1)10^8}{2\pi\nu}. \quad (53)$$

The R.M.S. value of the pressure induced between the rotor brushes by rotation is (*see* above)$=\frac{EA_1\bar{I}_1n}{\sqrt{2}}$ volts.

Since the pressure due to rotation is in phase with the stator current, the angle of phase displacement of the rotor current relatively to the pressure of rotation is

$$[\pi-2\pi\nu(t_1-t_2)].$$

Therefore, the power is

$$=\frac{EA_1\bar{I}_1nI_2}{2}\cos[\pi-2\pi\nu(t_1-t_2)]$$

$$=-\frac{EA_1\bar{I}_1I_2n}{2}\cos 2\pi\nu(t_1-t_2).$$

The negative sign denotes the motor action.

Substituting for $I_2\cos 2\pi\nu(t_1-t_2)$ from equation (53) we have—Power (in watts)

$$=\frac{EA_1I_1n}{2A_2D_2}\left[A_1D_1I_1+S_1I_1108-\frac{\bar{P}\sin 2\pi\nu t_1}{2\pi\nu}10^8\right]$$

$$=\frac{EA_1n}{2A_2D_2}\left[(A_1D_1+S_1108)\bar{I}_1^2-\frac{PI_1\sin 2\pi\nu t_1 10^8}{2\pi\nu}\right]. \quad . \quad . \quad (54)$$

The torque is obtained by dividing the power by the angular velocity of the rotor—*i.e.*, by $2\pi\times$ speed (in revs. per second).

Hence the torque is

$$=\frac{60EA_1}{4\pi A_2D_2}\left[(A_1D_1+S_1108)I_1^2-\frac{\bar{P}I_1\sin 2\pi\nu t.10^8}{2\pi\nu}\right]. \quad . \quad . \quad (55)$$

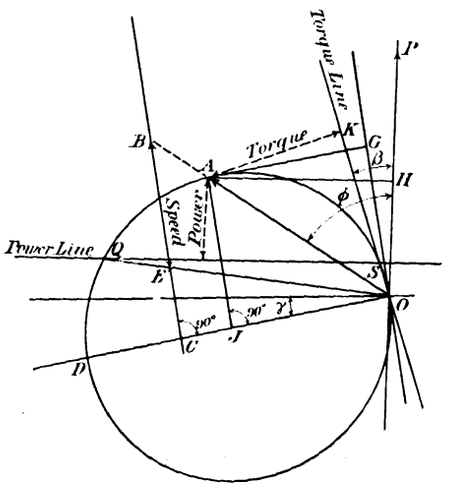


FIG. 16.

NOTE.—In this figure the angle γ is the angle α referred to in the calculations.

In Fig. 16 let the line OG be drawn as a tangent to the circle at O. Then we have

$$\frac{OA}{OJ}=\frac{OD}{OA'}$$

Therefore $OA^2=OD\,.\,OJ=$ constant $\times$ AG.

Therefore $\bar{I}_1^2$ is proportional to AG.

Further, $AG=I_1\sin(2\pi\nu t_1-a)$,

$AH=I_1\sin 2\pi\nu t_1$.

Now we have $AG=\bar{I}_1^2/OD$, therefore the torque is

$$=\frac{60EA_1}{4\pi A_2D_2}\left[(A_1D_1+S_1108)\bar{I}_1^2-\frac{PI_1\sin 2\pi\nu t_1 10^8}{2\pi\nu}\right].$$

It is generally more convenient to deal with R.M.S. values of the current, in which case we get

$$\text{Torque}=\frac{2EA_1(A_1D_1+S_1108)OD\,AG60}{4\pi A_2D_2}-\frac{2PEA_1108AH60}{8\pi^2A_2D_2\nu}$$

$$=kAG-k'AH$$

$$=kI_1\sin(2\pi\nu t_1-a)-k'I_1\sin 2\pi\nu t_1,$$

in which $k=\frac{2EA_1(A_1D_1+S_1108)OD60}{4\pi A_2D_2}$ and $k'=\frac{2PEA_1108\cdot60}{8\pi^2A_2D_2\nu}$.

Now the expression $kI_1\sin(2\pi\nu t_1-a)-k'I_1\sin 2\pi\nu t_1$ may be written in the form $KI_1\sin(2\pi\nu t_1-\beta)$, in which

$$K=\sqrt{(k\sin a)^2+(k\cos a-k')^2}$$

and $$\tan\beta=\frac{k\sin a}{k\cos a-k'}.$$

But $I_1\sin(2\pi\nu t_1-\beta)$ is equal to AK. *Therefore, the torque is* K . AK = K × [*the perpendicular distance of the extremity of the current vector from the line* OK].

It may be shown that the power may be represented by the perpendicular distance of the extremity of the current vector from another line drawn at a certain angle to the ordinate axis. This line may be found in a similar manner to that in which the torque line was found. The following considerations, however, lead to a simpler solution. The power must be zero in the two following cases: (1) When the torque is zero; (2) when the power is zero. Hence the power line must pass through the points SQ in Fig. 16.

The results deduced by the aid of the foregoing theory will now be compared with some experimental results.

(*To be continued.*)

ERRATUM.—We regret that Fig. 14 was incorrectly reproduced in last week's issue. We therefore give herewith the correct Fig. 14,

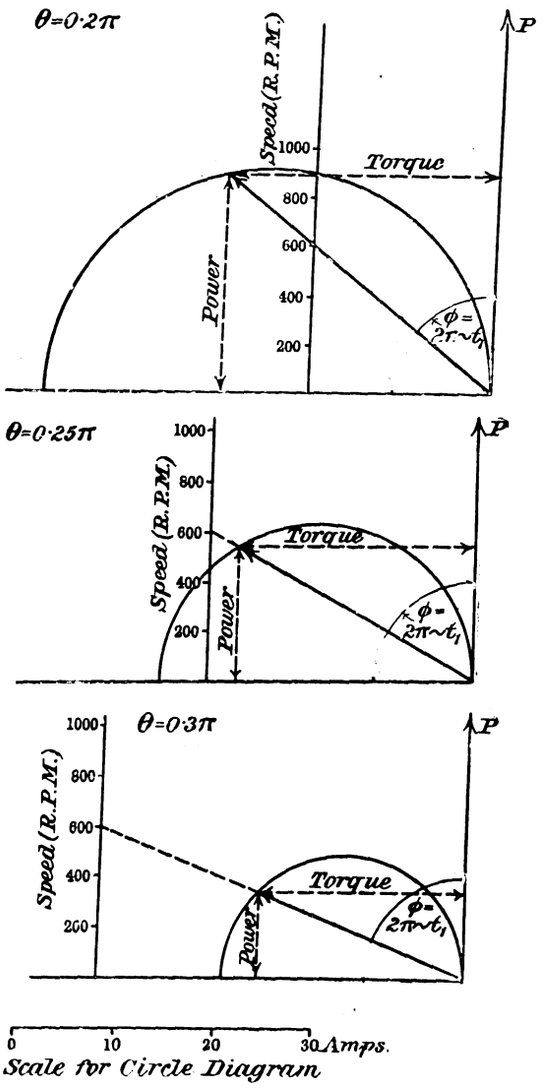

FIG. 14.

and must ask our readers to substitute this figure for that given last week.—ED. *E.*

Proposed Railway under the Lagoon at Venice.—According to the "Journal" of the Royal Society of Arts, it is now proposed to connect Venice with the island of Lido by a tunnel under the lagoon. This island, a favourite summer resort of the Venetians on account of its unrivalled beach and excellent sea-bathing, is situated on the Adriatic, about two miles from the city. The terminus of the line would be in a central position, close to the Piazza di San Marco, and the Riva degli Schiavoni, at about 26¼ ft. below the sea level. The tunnel, 2¼ miles in length, would pass in a straight line, under the islands of La Giudecca and San Georgio, to the terminus at Lido, a spot called the Quattro Fontane. The line and lifts would be worked by electricity, and trains could perform the journey in five minutes.

CORRESPONDENCE.

THE PUBLIC AND THE ELECTRICAL EXHIBITION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I must congratulate you on your ability in fault-finding. At the first attempt you have discovered the leak where the current is running to earth, rendering somewhat inefficient a machine which, for the past 10 days, should have been working continuously on full load without excessive temperature rise.

To forsake metaphor (which teems with pitfalls for the unwary) and to come to ordinary language, the promoters of the Olympia Exhibition do not appear sufficiently to have differentiated between the two classes to which an electrical exhibition must be made to appeal, viz., engineers and the general public. The former regard Olympia in the light of a glorified showroom where they may see the various examples of modern electrical equipment with a minimum of trouble. In providing for their wants, the promoters have succeeded. Technical visitors, who 12 months ago knew all about the Exhibition and where it was being held, have appeared in fair numbers, and are satisfied with what they have seen, for though there is not anything startlingly new, there is plenty of interest and the exhibitor is satisfied in that respect.

But there has not been the same success as regards the general public. Many of the exhibitors wish to appeal to the public, quite apart from the technical man, for it is to the public as a purchaser that we must look largely in the future if the electrical industry is to be kept busy. So far, however, the attendance of the layman has been very much smaller than at the last electrical exhibition at Olympia, which is to be regretted, and shows a lack of organisation somewhere. In addition, it is to the interest of *all* classes of exhibitors that the public should be attracted to Olympia in large numbers. The cost of exhibiting is a heavy item at any time, but in these days of excessive competition it can ill be afforded by many. Therefore, we standholders look to a good "gate" to help to recoup us for our outlay; but as things are at present, I am afraid we shall be disappointed.—I am, &c.,

London, Oct. 3. EXHIBITOR.

INTERNATIONAL COMPETITION IN PRACTICAL TELEGRAPHY AT TURIN.

As announced in THE ELECTRICIAN, there has been held, in connection with the Turin Exhibition, an international competition in practical telegraphy, which was open to British telegraphists and others in the service of administrations which are members of the Telegraph Union. The competition took place from Aug. 22 to 28. The full regulations governing the competition were given in THE ELECTRICIAN for Oct. 21, 1910, and will also be found in "The Electrician" Electrical Trades' Directory and Handbook for 1911, pp. 642-4.

There were 226 competitors, of whom 114 were employed by the Italian Telegraph Administration and 112 by foreign departments. There were 31 from Austria, 24 from Germany, 15 from France, 8 from Spain, 7 from Hungary, 6 from Belgium, 5 from Switzerland, 4 from Roumania, 2 each from Brazil, Greece, Turkey, Servia and Sweden, 1 from Great Britain and 1 from the South African Union. Among the competitors were 9 females (5 Italians, 2 Swedish, 1 French and 1 Austrian). On Aug. 18 the jury (an international one) assembled, and after an address by Comm. G. Greborio, Inspector-General of Italian Posts and Telegraphs, it was decided to leave to a sub-committee, presided over by Ing. Mirabelli, certain points raised by the delegates as to the use of particular types of instruments, &c. On Aug. 20 the jury approved the instructions as to the performance of the tests and also the conclusions of the sub-committee as to the apparatus to be employed. On Aug. 21 the competitors were received at the Turin central telegraph office, which was beautifully decorated for the occasion. Comm. Greborio welcomed the visitors, and Prof. C. Montu delivered an interesting address on telegraphy. On the morning of Aug. 22, after the apparatus was tested and found to be in good working order, the first test was commenced.

In the *Morse trial* there were 117 competitors, 43 of whom were classified and 40 received rewards. The winners of the two Grand Prizes were Italians—viz., MM. Schinetti (cup given by the Italian Minister of War and 1,000 frs. by the Minister of Posts and Telegraphs) and Padroni (cup and 1,000 frs. by the State Railway Administration). Gold medals were awarded to the following: MM. d'Agostino (Italy) (and gold watch), Garonimi (Italy) (and 500 frs.), Ironci (Italy) (and 500 frs.), Malasoma (Italy) (and gold chronometer), Baldaro (Italy) (and 400 frs.), Landini (Italy) (and 300 frs.), Woettki (Germany) (and 200 frs.), Staffa (Italy) (and 200 frs.), Balsamo (Italy) (and 200 frs.), Donot (France) (and bronze statuette), Ledrus (Belgium) (and 100 frs.), Dalcero (Italy) (and 100 frs.), Schuwerack (Germany) (and 100 frs.), Cannas (Italy) (and 100 frs.), Scaglioni (Italy) (and 100 frs.), Eichholz (Germany) (and bronze statuette), Testi (Italy) (and clock), Mdlle. Planck (Sweden) (and 50 frs.), Bernand (France) and de Rooy (Belgium). In addition, 10 silver and 8 bronze medals were awarded.

For the *Hughes trial* there were 76 competitors, of whom 67 were classified and 28 received a reward. Grand Prizes were awarded to MM. Martens (of Belgium) (cup given by the Foreign Minister and 1,000 frs. by the Minister of Posts and Telegraphs) and Zillig (of Germany) (cup given by Naples Municipal Council and 800 frs. by the Minister of Posts and Telegraphs). Gold medals were given to MM. Fleyel (Germany) (and silver knives and forks), de Rooy (Belgium) (and 500 frs.), Kubelka (Austria) (and 400 frs.), Bradl (Austria) (and 300 frs.), Schindler (Austria) (and 200 frs.), Haussmann (Germany) (and gold watch), Krumm (Germany) (and 100 frs.), Pernt (Austria) (and 100 frs.), Hienke (Germany) (and 100 frs.), Bontez (Belgium) (and 100 frs.), Czinte (Hungary) and Boixeda (France). There were also 8 silver and 6 bronze medals.

In the *Baudot test* 80 competitors entered, 76 of whom were classified and 22 received awards. Grand Prizes were given to two Frenchmen, MM. Chapius (cup and 1,000 frs.) and Maurel (cup and 800 frs.). Gold medals were given to MM. Sol (France) (and 500 frs.), Constant (France) (and 400 frs.), Rocca (Italy) (and 300 frs.), Berti (Italy) (and gold watch), Valente (Italy) (and 200 frs.), Mdlle. Aymar (Italy) (and 100 frs.), Batocchi (Italy) (and 100 frs.) and Pernt (Austria) (and 100 frs.). Six competitors obtained a silver medal and six a bronze medal each. The prize which was reserved for the groups of competitors belonging to the State taking part in the tests with three competitors, one for each system and winning a prize in each of them, has been obtained by Italy. It is a bronze work of art (1m. 50 high on a 80m. diameter) by Zanelli.

There was no competition for the championship prize, as none of the competitors obtained prizes in each of the trials.

It is stated that certain competitors attained a very high speed, largely exceeding 1,000 words an hour, both in transmitting and receiving. This high speed, however, was obtained at the expense of accuracy, for it appears that errors made (signals altered, badly made or insufficiently spaced) prevented them from reaching the position they hoped to attain. With the Hughes apparatus, M. Martens, of Belgium, who was classed first with 122 points above his nearest competitor, succeeded in transmitting in one hour, without any trouble and without error, a total of 1,502 words, the words having an average length of 7¼ characters, and 12,767 characters or signals being transmitted.

With the Baudot apparatus the results were also very good, and the winners in the competition attained almost the highest possible points.

On the evening of the distribution of prizes a banquet was given at which the organisers, the members of the jury and of the committee, as well as the competitors, were present. The Minister of Posts and Telegraphs, Signor Calissano, presided.

LEGAL INTELLIGENCE.

Appointment of Electrical Inspectors.

At Clerkenwell (London) Police Court yesterday (Thursday) Mr. Bros resumed the hearing of the application by Mr. C. S. Sayer, of Messrs. Macdonald, Sayer & Co. (Ltd.), for the appointment of an electrical inspector for the St. Pancras District. Applicant's firm was taking current from the Borough Council for power and lighting, and a dispute had arisen between the parties as to a particular type of fuse which the Council desired consumers to adopt. There was no other complaint against the efficiency of the Council's supply. A good deal of discussion arose as to the legal position and as to the authority of the magistrate to appoint an electrical inspector. The application was ultimately adjourned to enable applicant to obtain legal advice.

COMMERCIAL AND INDUSTRIAL SECTION.

MUNICIPAL, FOREIGN & GENERAL NOTES.

BRITISH NOTES.

Associated Municipal Electrical Engineers (Greater London).—At the last meeting the Association elected the following officers for the year 1911-12:—

President: Mr. W. C. P. Tapper (Stepney); *Vice-presidents:* Messrs. F. A. Bond (Battersea), L. L. Robinson (Hackney) and A. H. Shaw (Ilford); *Hon. Treasurer:* Mr. G. G. Bell (Hammersmith); *Hon. Auditors:* Messrs. J. G. Bruce (Willesden) and E. Calvert (Finchley); *Hon. Secretary:* Mr. Norman Staniland, Electricity Works, Hornsey, N.; the Council is composed of Messrs. S. W. Baynes (St. Pancras), J. H. Bowden (Poplar), H. H. Couzens (West Ham), C. S. Davidson (Barnes), A. J. Fuller (Fulham), F. Hill (Hammersmith), W. Innes (Poplar), C. Newton Russell (Shoreditch), P. E. Rycroft (Heston), E. Sayer (Hampstead), A. H. Seabrook (St. Marylebone) and W. C. Ullmann (East Ham).

By kind permission of the Institution of Electrical Engineers, the Association meetings are now held at the new Institution buildings, and the dates of the meetings will be fixed in advance. The Association had under consideration at their meeting various matters of interest, including the question of a defensive combination between the power and light authorities (including gas companies) in times of general strikes. The Association visited the Electrical Exhibition at Olympia on Oct. 4.

Barrow-in-Furness.—At the monthly meeting of the Corporation on Monday it was decided, on the recommendation of the Highways & Lighting Committee, to replace existing gas lighting in Abbey-road, from the central station to the Furness Abbey tram terminus, and also in Roose-road, from Salthouse Bridge to the tram terminus, by electric lighting. The electric lighting is to be by means of metal filament lamps from span-wires fixed between the tram poles on either side of the road.

The total length of road over which gas lighting is to be displaced is over two miles, and the number of electric lamps to be erected 162. This decision has been arrived at as a result of a prolonged test between the two illuminants, in which the superiority of electric lighting along the roads planted on both sides with trees has been very marked.

Extensions of mains at an estimated cost of about £990 are being carried out, in connection with the supply of power to Messrs. Burt, Boulton & Haywood's sawmills at Devonshire Dock, where motors aggregating about 165 H.P. are being installed.

Bedford.—The new highway depot of the Beds County Council is to be supplied with electrical energy for light and power, and the supply mains are also to be extended to the Isolation Hospital.

A new coal bunker has been erected at the electricity works.

Belfast.—An unopposed inquiry was held on Tuesday into the application of the Corporation for sanction to borrow £40,000 for extensions of the electricity undertaking, including £12,850 for plant, £9,560 for mains, £6,100 for feeders, £8,550 for services, and £2,000 for meters, time switches, &c. The city electrical engineer (Mr. T. W. Bloxam), supplied technical details.

Bermondsey.—Friction has arisen between the Council and London County Council in regard to loans for extensions of the electricity undertaking.

It was reported to the Borough Council on Tuesday that although the contracts for additional plant had been let the County Council declined to sanction the loan for the purpose. The County Council asked for certain information as to the financial position, &c., of the undertaking, but the Borough Council thinks that London County Council is not entitled to the information. In a recent letter the Comptroller of London County Council reported that he noted that the Borough Council had accepted tenders for the proposed plant and buildings, and he reminded them that it was the opinion of the Finance Committee that no liability for expenditure which was to be made the subject of a loan should be incurred until the loan sanction was obtained.

Reporting upon the position, the Electricity Committee of the Borough Council states that they have no alternative, in view of the liability having been incurred, but to recommend the amount for payment, and in doing so they warn the Council that should the County Council refuse their sanction to the loan (£18,563), and an appeal to the L.G. Board fail, any liability incurred by the Council in the matter will have to be met out of the general fund, probably involving a heavy increase of the rates.

Birmingham.—The work of laying supply mains in Moseley is proceeding apace.

Mains have been laid and supply is available in several streets, and work is in progress in other thoroughfares. A show-room has been opened in Alcester-road to meet the convenience of residents in Moseley and King's Heath, who will be able to see a display of electric motors, lighting fittings, ovens, radiators, hot-plates, kettles, irons, &c. The current for the supply of Moseley will be supplied from Summer-lane station through the sub-station at Balsall Heath. The Electric Lighting Committee have secured a site for a sub-station at Harborne for the general supply of Harborne, and also to provide a duplicate bulk supply to Selly Oak. The question of a sub-station for the supply of King's Norton and Yardley is also engaging the attention of the committee.

A tramcar accident took place on the Dudley-road route on Sunday night, resulting in the death of one and injuries to 15 passengers.

One of the late cars from Birmingham to Bearwood was ascending Cape-hill, and when half-way up it stopped to pick up several passengers. On attempting to re-start the driver found that he could not make any progress, and the car began to run back. The brakes were applied, but they refused to act, and in a short time the car was running at high speed down the steep hill. It came into collision with another car which was coming up the hill, and the two were partially telescoped. Some passengers jumped and others were thrown off. The two interlocked cars rushed down the incline, and at the bottom ran into a stationary car.

Col. Yorke will hold an inquiry into the circumstances of the accident to-day (Friday).

British Electrical & Allied Manufacturers' Association (Incorporated).—Next meeting of Council at Olympia, W., on 12th inst., at 2:30 p.m.

Carluke.—At a public meeting last week it was decided to petition the Clyde Valley Electric Power Co. to extend their mains to the district. Great dissatisfaction is expressed at the charges made by the local gas company.

Caversham.—Over 100 of the street lamps are now converted to electric lamps, and the work of substituting electric for gas lighting in the remainder of the district is making rapid progress.

Electric current is supplied by the Reading Electric Supply Co. In each of the old lanterns two electric globes are being placed, in addition to a reflector, and the light thus obtained is much superior to that provided by the gas lamps. The members of the Council estimate the saving in the cost of lighting by electricity at £100 a year.

Cheltenham.—Application is to be made to the Board of Trade for a provisional order amending the Cheltenham Electric Lighting Orders of 1890-1900 by extending the area of supply to the parishes of Leckhampton, Swindon, Prestbury, Bishop's Cleeve, Southam, Brockhampton, Woodmancote, Badgeworth, Shurrington and Up Hatherley.

Eastbourne.—Messrs. R. H. & J. Pearson, who are organising an electrical exhibition in November, are to be supplied with electrical energy at 1½d. per unit for exhibition purposes.

Ellesmere Port.—The Urban Council have unanimously resolved to apply for a provisional electric lighting order. A special committee has been appointed to deal with electricity supply.

Fleetwood.—The L. & Y. Railway Co. has asked for a reduction in the price of electrical energy supplied by the Council.

About four years ago the Company agreed to pay 3d. per unit for lighting and 1½d. for power, but the units consumed have risen from 41,376 to 114,957. Owing to the unsettled state of the coal trade and the possibility of an increase in price, the Council have decided not to grant an immediate reduction, but if the cost of coal does not increase a rebate will be granted of ¼d. per unit for power and ¼d. for light between Sept. 30 and March 31.

Fulham (London).—A new coal bunker, with a capacity of approximately 1,000 tons, is to be erected at the electricity works.

Halifax.—The Tramways Committee have reorganised the duties of the various officers of their department. Mr. W. M. Rogerson has been relieved of his appointment as general manager of the tramways, so that, on account of developments in prospect, he will be able to give his whole time to his other work as electrical engineer. Mr. Caird and Mr. Galloway, traffic superintendent and tramways engineer respectively, have been selected as dual managers of the tramways in his stead.

Heston and Isleworth.—Experiments are being made in the lighting of High-street with Jandus arc lamps.

Hornsey.—On Tuesday an unopposed enquiry was held into the application of the Council for sanction to borrow £500 for the purchase of land for extensions of the electricity works.

Hospital Lighting.—Bedford Council have decided to wire the isolation hospitals.

Crossley Hospital (Mirfield) is to be wired, and electric current will be supplied by Mirfield Council by overhead wires.

Johnstone.—The Council are considering the question of extending their gasworks; also the Council are ascertaining the cost of erecting electricity works.

Digitized by Google

ELECTRICITY SUPPLY TABLES AND DATA.

This Valuable Set of Tables and Engineering Data relating to Electricity Supply and to Electric Traction on Railways and Tramways in the United Kingdom, the Colonies, and some important places abroad, is now ready, and can be obtained complete in handy book form, price 6s. 6d. post free, or on very hard paper for rough or constant use, price 8s. 6d. post free. A complete Index is included.

Kingsbury (London).—At the last meeting of the Council the chairman (Mr. J. Diaz) announced that a supply of electricity was now available in the district.

The North Metropolitan Electric Power Supply Co. had, he said, built a sub-station in the parish, and in his opinion and in the opinion of many experts, electricity was the best for either public or private lighting and power. He hoped that Hendon Council would see their way to light up the west side of the Edgware-road, beginning at the northern boundary, all along Collindale and West Hendon, the Broadway, Cricklewood, Cricklewood-lane, Child's Hill, and even to introduce it within the whole of their principal district, including Golders Green and the Garden Suburb. If they did that it would be more efficient and cheaper in the long run than the incandescent gas mantles, the electricity being more reliable and possessing greater illuminating power. He also stated that their electric lamps in Kingsbury and on the Kingsbury side of Edgware-road cost less than the incandescent gas lamps in Hendon area.

L.C.C. Tramways.—London County Council have applied to the City Corporation for consent to the construction of a tramway in Bishopsgate as far as Middlesex-street, and from Charles-street to a point near Ludgate-circus, via Farringdon-road and Farringdon-street.

Stepney Council decided on Wednesday to oppose the proposal of the County Council to reconstruct the present horse tramways from West India Docks to Victoria Park on the overhead system.

Manchester Smoke Abatement Exhibition.—Everything points to a success for this exhibition. Apart from the good work of the organisers, the fact that the exhibition will be held in a district where the need for smoke abatement is pressing, and at the time of year when the evil effects of a smoky atmosphere are most apparent, coupled with the movement for cleaner cities, will help materially in securing the attendance of large numbers of factory and works managers and also of the general public. The exhibition will be held in the City Hall, Manchester, from Nov. 10 to 25 next.

Newport (Mon.).—At a private meeting of the Electricity and Tramways Committee on Monday it was decided to recommend the Council to appoint a general manager to take supreme control of the tramways undertaking, Mr. Collings Bishop to retain the position of electrical engineer. The committee did not fix the remuneration for the new manager, but some members said they were desirous of getting a first-class man, and £1,000 per annum was mentioned.

Poplar and Stepney Electricity Supply Agreement.—Poplar (London) Council have approved the following heads of an agreement with regard to reciprocal and stand-by supplies of electricity between the two councils:—

(1) Stepney to afford supply to Poplar under the present agreement, pending Poplar extensions, to the year 1913; (2) Poplar to afford supply to Stepney from 1913 to 1917, or until such time as the maximum demand of Stepney reaches, say 7,270 kw.; (3) Stepney not to complete extensions until 1916 at the earliest date, or until the aforesaid demand of 7,270 kw. is reached; (4) after the period of supply by Poplar to Stepney, Poplar to be under obligation to take from Stepney equal bulk supply as Stepney has taken from Poplar, before Poplar makes further extension, Stepney, however, to have preference of extension at such time; (5) three weeks' supply of coal, based on winter consumption, to be kept by each party immediately at hand.

The Electricity Committee, reporting on the agreement to the last meeting of the Council, stated that the proposals would involve the laying down in 1913, at an approximate cost of £20,000, of a further 3,000 kw. generating set for the accommodation of which provision had been made in the scheme for extending the station buildings. It would be necessary to provide mechanical means of unloading and conveying coal, in order to safeguard the coal supply as well as to reduce the cost of handling, and they recommended that Poplar should provide stand-by for Stepney until 1917.

P.O. Wages.—Last week the Postmaster-General (Mr. H. Samuel) received a deputation from the National Joint Committee of Postal and Telegraph Associations.

Mr. W. Davis, chairman of the Association, said the deputation represented 70,000 organised employés of the Post Office service, who were unanimous in their demand for a Select Committee of the House of Commons to consider their grievances. The result of the interpretations placed upon the findings of the Hobhouse Committee by the Department had been to embitter the Post Office servants. The engineer linesmen and stores employés complained of long hours, low pay and the preponderating percentage of unestablished force.

Mr. Samuel, in reply, said that he had declined requests from various Associations to reopen on his authority the main scales of Post Office wages laid down by the Hobhouse Committee; but they came now with a different request—namely, that the Government should invite the House of Commons to appoint another Select Committee to review the decisions arrived at by the Hobhouse Committee. He himself was not opposed to another Committee of the House of Commons enquiring generally into the conditions of Post Office service, but it was a question of what interval should be allowed to elapse between the holding of one enquiry and the holding of another. He could not give a definite reply, either affirmative or negative, to their request at that moment without consultation with his colleagues.

Rail-less Trolley Traction.—Failing other means of communication between Southall and Twickenham via Hounslow, it has been decided by Heston and Isleworth Council to include in their general bill clauses to confer powers to equip routes on the rail-less trolley system.

St. Helens Corporation have appointed a committee to report upon the question of utilising the rail-less trolley system for projected extensions of the local tramways.

Dundee Council have decided to equip the Clepington-road route on the rail-less trolley system.

The Tramways Committee are to consider the question of the existing tramway along Cranbrook-road or the equipment of the route on the rail-less trolley system.

The Northampton Tramway Committee have instructed their manager (Mr. J. Gottschalk) to report as to the working of the Leeds and Bradford experiments in rail-less trolley traction.

Rotherham Corporation have ordered the Maltby route to be equipped on the rail-less system.

The deputation recently appointed by Edinburgh Council to visit Leeds and Bradford rail-less systems of traction in those towns have issued their report, which states that the extended trial of the system has now confirmed the favourable opinion formed in July last as to the reliability, simplicity and economy of the system.

The report further states that the road formation over which the present equipment at *Bradford* operates is partly paved with granite setts, but for the greater part of the road is ordinary macadam. No special treatment was given to the road, and the deputation could trace no evidence of any extraordinary wear upon the road. It was not anticipated that the surface would suffer from the running of the trolley car. Electric current was supplied by the Corporation at 1d. per unit, and the current used in the driving of the car was about 0·95 unit per car-mile, about one-half the current used on an electric tramcar. The capital cost of 1¼ miles had been at the rate of £1,734 per mile, the two cars costing £700 each. The deputation did not experience any discomfort from vibration. The manager of the Bradford tramways puts the cost of operating at less than 5½d. per car-mile.

At *Leeds* the new line was opened in the middle of June last. It commences right in the centre of the city, and proceeds thence in a radial direction for a distance of four miles (one mile along a busy street crowded with vehicular traffic) until it reaches the Farnley outskirts. So far, the experience of Leeds Corporation in the working of the new line had been in every way encouraging. There had been no interruption in the working of the line, and there had been no accidents, notwithstanding the congestion of the traffic on portions of the route. The surface of the road over which the cars run is paved partly with wood and partly with granite within the city, whilst in the outskirts it is ordinary macadam formation. The running of the car is smooth and unattended by any abnormal vibration. The capital cost of the four miles route on the new system was £1,246 per mile, and the cost of the cars to hold about 56 passengers £700 per car. The actual revenue per car-mile in Leeds is 8·78d., and the total operating costs 5½d. per car-mile (exclusive of interest and redemption of capital).

In summarising the information obtained, the Edinburgh deputation thought it right to say that, notwithstanding that the system had only been on trial for a comparatively short period in this country, they had formed the opinion that that method of conveyance was capable of satisfying the requirements of many districts in and around Edinburgh, not already provided with public transit, in a practical and economical manner. It offered the great inducement of being able to provide an excellent service at a minimum cost, enabling routes to be equipped that might under other systems prove quite unprofitable. The financial advantages compared with overhead trolley tramways were the reduced cost of equipment (being not more than one-seventh part of the cost of constructing and equipping the overhead tramway), a saving in maintenance of permanent way, and the reduced costs of operating. The pre-eminence of the trolley car in comparison with the motor bus, on the other hand, was proved by the easy running, its freedom from smoke or odour, the reduced vibration of the car in motion, and its freedom from shock in starting and stopping, and, above all, its reliability. Therefore, they consider it eminently suitable for new districts which cannot be expected to provide a profit upon the capital cost of tramways. Whilst providing for the development of new districts, the system could be readily transformed into, and completed, as a regular overhead tramway, should the traffic increase so as to exceed the relatively limited capacity of the trolley car. At what stage the transition from the one to the completed tramway should take place was a matter to be determined by experience still to be acquired, by the development of the conditions of trade, and by the amount of traffic which the system was capable of overtaking. Further, the alleged objection to tramways being laid along suburban roads was done away with, because the roads were [illegible]

Digitized by Google

free from rails, and its overhead equipment was so unobtrusive that one speedily became unaware of its presence. The deputation direct special attention to the policy adopted at Bradford of creating a circular route, bearing such similarity, as Bradford did, to the radial routes of the Edinburgh system, stretching out from a common centre in diverse directions, but quite unconnected at or near to the extremities, the object in view being the uniting of those divergent routes by a new circular route.

The deputation, confining themselves to the terms of their reference, do not suggest any specific route or roads suitable for the introduction of the rail-less system into Edinburgh, but there are many suburban streets and roads within the city boundary where the system would be eminently suitable.

The report contains several photographs of street scenes in Leeds and Bradford in connection with the working of the system.

In reply to a question, the chairman of the Leeds Tramways Committee (Ald. Tetley) stated at the Council meeting on Wednesday the total capital cost of the rail-less system of traction had been £7,600, the amount set aside for interest and sinking fund would be £690, and the average receipts per car-mile were 8·3d. A period of three months was quite an insufficient time for any reliable information on the question of profit to have been obtained.

Dronfield Urban Council have applied to Derbyshire County Council for the approval of a system of rail-less trams between Sheffield and Dronfield, but the County Council have asked for further particulars.

Reigate.—The Council have received sanction to the following loans for electricity supply :—

£1,292 to defray excess expenditure on transformers, services and armoured mains (for 13 years), £530 for excess expenditure on mains in conduits (23 years), £142 for excess expenditure on meters (three years), £4,859 for new engines, switchboard, &c. (17 years) and £1,118 for prospective expenditure on mains, services and transformers (15 years).

Application has been made to the L.G. Board for authority to defray the £423. 4s. 10d. deducted from the sanction for the new switchboard, out of renewals and contingencies fund account. The sum of £36. 4s. for sundries in connection with house services, &c., deducted from the sanction for extensions already carried out, will be defrayed out of the same account. In future a separate account will be kept of the expenditure under each sanction for loans.

Rotherham.—Sanction has been received to the following loans for tramway purposes :—

Land at Rawmarsh-road, £327 (repayable 60 years); buildings, £550 (20 years); machinery, £6,287 (16 years); cables, £14,780 (25 years); total, £21,944.

The Broom tramway route is to be extended to the borough boundary, and the Dalton line to Tarybergh.

Salford.—Mr. C. D. Taite has been retained by the Council, at a fee of 50 guineas, to report upon the proposal to instal an additional turbo-generator, &c.

Southborough (Kent).—The Council will apply for a provisional electric lighting order.

Southwark.—The Electric Lighting Committee have had under consideration a report from the borough electrical engineer (Mr. J. M. Kinghorn) on the hiring out of motors.

Mr. Kinghorn states that the system appears to appeal to a large number of consumers, and there was a probability of its being largely extended in the future. At present the practice of the Council was to depreciate arc lamps and other apparatus on the basis of a life of five years, which worked satisfactorily for such apparatus, as fittings, lamps, radiators, &c., which were always being superseded by improved apparatus. The case was different with motors, the useful life being not less than 15 years, and it was not possible to obtain for hire from the consumer a sum sufficient to cover depreciation and maintenance at that rate, so that, with every probability of the hire system increasing, there would be a serious deficit to be met on the hire account for at least five years unless the period was extended. The usual rate for hire was 10 to 12½ per cent. of the cost of the motor, and Mr. Kinghorn suggested that the cost should be written off in 10 years, thus making the scheme self-supporting. The Committee have decided to extend the time from 5 to 10 years.

Stepney (London).—The Electricity Committee have expended the £500 advanced to them for wiring customers' premises on the hire purchase system, and another sum of £500 has been voted for the same purpose. £2,500 is also to be expended on meters, &c.

Stoke-on-Trent.—The Electricity Committee report that the aggregate amount of the accepted tenders in connection with the new electricity works is about £55,000, made up as follows :—

Jas. Howden & Co., turbo-generators, £8,905; British Westinghouse Co., rotary converters, £3,800, transformers, £384, and switchgear, £651; Bruce Peebles & Co., motor converters, £2,250, and motor-generators (D.C.), £225; Siemens Bros. Dynamo Works, motor generators, £2,385; Callender's Cable & Construction Co., mains and cables, £3,093. 10s. 10d.; Stirling Boiler Co., boilers, £5,040; Davenport Engine Co., cooling towers, £1,053; Grants (Ltd.), Burslem, buildings, £5, and power house buildings, £5,745; J. Meiklejohn, Stoke, buildings, £5; Acton & Co., steam pipes, &c., £1,128. 12s.; New Conveyor Co., coal bunkers, &c., £1,426; G. & J. Weir, steam feed pump, £113; D.P. Battery Co., storage battery, £91; Herbert Morris & Bastert, 15-ton crane, £229; British Westinghouse Co., electric feed pump, £180.

Submarine Telegraph Cable Capacities.—Mr. Gilbert Rosenbusch (who presumably writes as an expert), in the course of a letter appearing in "The Times" for Oct. 4, writes as follows :—

For years transmitting and receiving instruments have been available having a speed immeasurably greater than that of the cables on which they operate. It must be evident, therefore, that if some form of cable were available which would have a greater speed of transmission than those at present in use, the laying of such a cable would be justified, as the far lower rate per message possible would force the cable companies to meet this competition.

The inherent peculiarity of existing submarine cables, known as electric capacity, has been the stumbling-block, and for many years the engineers of the cable companies have pooh-poohed the idea of counteracting this by electric inductance.

Were a cable so constructed that these electric difficulties were overcome, not only would a much greater speed be possible, but telephoning across the Atlantic might be practicable. This latter feature is of particular interest at this juncture, owing to the impending nationalisation of the telephone system in this country.—GILBERT ROSENBUSCH.

Another writer in "The Times," described as "An Engineering Correspondent," writes on practically the same subject, and with almost the same absence of knowledge of what has been done of late in connection with submarine telegraph cables. The editor of "The Times," in commenting upon this latter correspondent's letter, makes the remarks following :—

The above correspondent appears to have overlooked the fact that the suggestion to compensate the effect of capacity by adding inductance is due to Mr. Oliver Heaviside [the correspondent referred to credits Prof. Cuntz, of America, with this discovery]. He has also omitted to mention that the idea of continuous "loading," as opposed to "loading" by coils, has long been known, and that it has been successfully applied in the case of several telephone cables. Further, it is necessary to observe that the statement [by this correspondent] that "the speed of this (Cuntz) cable is at least five times that of existing cables" must be accepted with the utmost reserve. It possibly relates to a laboratory test, but it is obviously incorrect as applied to an Atlantic cable.

We may add that, taken in conjunction with Mr. Rosenbusch's letter, it is clear that the schoolmaster is abroad. Mr. Rosenbusch evidently has a poor opinion of the capacity of the consulting and chief engineers of the cable companies. Those who are more intimately acquainted with the subject do not altogether share his views.

Teignmouth.—The Council are to consider in committee an application by Dr. J. W. Purves for their assent to a proposed application for an electric lighting order.

The Telephone Purchase.—The "Daily Mail" states that the priced inventory (which our contemporary describes as "the greatest sale catalogue ever compiled") of the trade assets of the National Telephone Co. is nearing completion. We are told that this is the work of 650 experts. According to this estimate the total amount the Post Office will require to hand over to the company is between £14,000,000 and £15,000,000. We have no means of checking these stupendous figures.

Walthamstow.—The Council will maintain and repair electric light installations at the various schools at actual cost plus 5 per cent. for establishment charges.

Sanction has been received to the borrowing of £6,634 for feeder cables and spare stoneware conduits.

West Hartlepool.—The Council further considered on Friday the proposal to purchase the local tramways.

The Tramways Committee recommended the purchase of the section of the Hartlepool line within the West Hartlepool borough boundary; and also recommended the Council to obtain the necessary powers for working the line as well as the Park and Foggy Furze lines, and for constructing certain additional lengths of routes.

Mr. Martin moved, as an amendment, that the Council negotiate with the tramway company with a view to the company accepting an extended lease of 42 years. He declared that the Corporation could not carry out the scheme of municipalisation under £120,000. Tramways (he said) never had paid, and never would pay in that district.

Ultimately the amendment was defeated, and the recommendations of the committee adopted.

Worksop.—St. Cuthbert's College is to be wired, and electric current will be supplied by the Council.

Worthing.—Sanction has been received to a loan of £4,532 for the extension of the electricity station, buildings and plant.

G.E.C. Athletic Club.—The G.E.C. athletic club opened their football season on Saturday last on their new ground at Willesden with a stirring game between head office (Osram F.C.) and Queenhithe branch (Magnet F.C.).

The game was a very fast one, and after a hard fight the result was a win for the Osram team by 3 goals to 2. The secretary would be pleased to hear from any club connected with the industry with a view to fixing up matches for the coming season.

Digitized by Google

COLONIAL AND FOREIGN NOTES.

Australasia.—The "Australian Mining Standard" says a satisfactory agreement has been arrived at between Shepparton (Victoria) Water Trust and Shepparton District Council for a joint pumping and electricity scheme. Mr. Crossle (of F. A. McCarty & Co., Melbourne) has compiled a list of 60 intending consumers, mostly occupiers of large stores and shops. The District Council will erect the works and supply current to the Water Trust. The total annual revenue is estimated at £2,240 and the gross profit at £825.

Amongst his criticisms of the Sydney telephone system, Mr. H. W. Ramsay Sharp, who was appointed to enquire into the efficiency or otherwise of the service, says the electrical engineers have too much routine work, with the result that important technical matters cannot receive proper attention, and the salaries of some of the officials are out of proportion to their responsibilities; for instance, the salary of the chief electrical engineer of the Commonwealth is only £750 (£50 more than he received when State engineer of Queensland), and that of the telephone mechanician, Sydney, with a staff of 200 permanent and an average of 500 temporary men under him, is £252. Mr. Sharp further states that the majority of switchboards at branch exchanges and the present central switchboard are out of date, and recommends that sufficient additional junctions, B positions and order wires be promptly installed, that every branch exchange with over 500 subscribers be fitted with multiple switchboards, and that the erection of new switchboards be hastened by the employment of larger erecting staffs.

Canada.—The U.S. Consul at Winnipeg, says the City of Winnipeg will be prepared within a few months to sell electrical energy.

The great plant at Point du Bois, costing £450,000, and capable of generating 100,000 H.P., is nearing completion. While the city is contemplating purchasing the street car system, it may also arrange to take over the power plant of the street railway company, which supplies power for the railway, and electricity for private lighting and for power. The rates for power at present: 6 cents per unit up to 50 H.P.; 4 cents from 50 to 100 H.P., and 3 cents over 100 H.P. Current for private lighting costs 10 cents per unit and for cooking 6 cents. Public lighting costs 11 cents per arc lamp per night, the total cost in 1910 being $42,977.

International Rubber Exhibition.—Mr. A. S. Manders, organising manager of the Rubber and Allied Trades Exhibition recently held in London, states that a rubber exhibition will be held in New York in September, 1912.

Italy.—The Soc. Anon. di Tramvie Elettriche Briantee has obtained a concession for construction and working of an electric tramway from Meda to Cantu. The Soc. Anon. per la Tramvia Elettrica Lucca-Pescia-Monsummano a concession for construction and working of an electric tramway from Lucca to Maggiano.

Peru.—The Soc. Electrica del Cuzco (Ltda.), the board of which is composed of Alquipa business men, has been formed to supply electric light and power in Cuzco. It is proposed to use water power from Lake Chincheros or from the river Vilcaiota for generating electrical energy.

South Africa.—The report of the Rhodesia Chamber of Mines for 1910 states that the imports into Southern Rhodesia included: Electrical machinery, £11,822; mining machinery, £182,502; electrical materials, £11,661; manufactures of iron and steel, £89,023; detonators and fuses, £18,995.

Sweden.—An electric power station is being constructed at Elfkarleby, and temporary plant is expected to be working by December.

Switzerland.—M. A. Palaz, of Lausanne, has secured an 80 years' concession for the construction and working of a rack and pinion electric railway from Villars-Chesières to Bretaye, at an estimated capital cost of £34,000.

The Telephone in War Time.—For the first time since its introduction, we think, effective control of the telephone has been organised. Italy, in connection with the political troubles which have arisen between that country and Turkey on the Tripoli question, has succeeded in effectively "bonneting" both the telegraph and the telephone, so far as concerns the leaking out of any news concerning the mobilisation of the Italian fleet and army during the past week or two is concerned. The efficiency of the Italian wireless telegraph arrangements is said to have been of material assistance in this connection. The Italians pride themselves upon the completeness of their wireless telegraphic equipments, thanks to Signor Marconi.

Wireless Telegraph Notes.—It is stated that a still further extension of the wireless telegraph station at the Eiffel Tower, Paris, has been decided upon. In 1910 large extensions were made, and these have pointed the way to a still further enlargement of the powers of the station. "The Times" of Oct. 4 gives the following additional information on this subject:—

The existing installation consists of three sections, placed in an underground depot on the Champ de Mars. The first of these, which employs solitary sparks at 10 kw., is an early system, now used only for short distances; the second, which emits discharges at 40 kw., serves for long-distance purposes; and the third is adapted for the use of musical vibrations at 10 kw. This last method has proved excellent in practice, and it is the one which is to be increased in power. The musical discharge has been found, even with the present limited conditions, to attain a wide range of action, and to enable messages to be transmitted at times when the state of the atmosphere induces electric perturbations which paralyse the emission of isolated sparks. The plant is now sending telegrams to a distance of 3,100 miles. The new station, which is to be put in hand at once, will have 225 H.P. available. The current will be provided by a Diesel motor, which will drive an alternator on the Bethenod system at 500 volts, with 1,000 periods, and the station will serve as the starting point for a vast network of wireless telegraphy, destined to link up the French colonial possessions with the metropolis. The Minister for the Colonies has propounded a scheme which will involve the creation of at least 10 high-power stations, and this project will be carried out if the installation on the Eiffel Tower proves to be satisfactory.

TRADE NOTES AND NOTICES.

TENDERS INVITED.

The directors of the GREAT WESTERN RAILWAY Co. invite tenders for one year's supply of telegraph instruments, telegraph apparatus (insulators, &c.), electrical wires and cables, telegraph ironwork and tools, telegraph dryselteries, electric light carbons, glass, acids, oils, paints, leather, indiarubber goods, zinc, antimony, brass, tin plates, iron and steel wire, sundries, &c. (tenders by 10 a.m. Oct. 16); also for three years' supply of baskets, waste, brasswork for carriages, &c., locks, ironmongery, tools, varnish, &c. (tenders by 10 a.m. Nov. 7. Specifications and forms of tender (on and after Oct. 23 in the case of the second group) from the Stores Superintendent, Swindon. Tenders to the secretary, Mr. A. E. Bolter, Paddington Station, London. See also an advertisement.

Tenders are invited up to Nov. 15 for supply of magneto switchboards, millammeters, relays, repeaters, copper wire and an electric motor to the Postmaster-General's Department in SOUTH AUSTRALIA, and up to No. 28 for the supply of ebonite ear-pieces, calculagraphs and brown stoneware insulators to the Postmaster-General's Department in VICTORIA. Specifications, forms of tender, &c., from the Commonwealth Offices, 73, Victoria-street, London, S.W. See also advertisements.

HAMMERSMITH (London) Borough Council invite tenders for the supply of various a.c. and d.c. motors. Specifications, form of tender, &c., from the borough electrical engineer, Mr. G. G. Bell, St. Fulham Palace-road, London, W. Tenders to the town clerk, Mr. H. Thompson, by 4 p.m. of Wednesday, Oct. 11. See also an advertisement.

GRIMSBY Corporation invite tenders for supply of paper-insulated lead-covered cables, house fuse and main service boxes. Specifications and forms of tender from the borough electrical engineer, Mr. W. A. Vignoles, M.I.E.E. Tenders must be in by first post Oct. 10.

The Tramways and Electricity Committee of BELFAST Corporation invite tenders for the supply of 2,000 ampere switchboard apparatus, field regulating rheostat and change-over switch. Specification and form of contract from the city electrical engineer, Mr. T. W. Rhodes, East Bridge-street, Belfast. Tenders to the town clerk, Mr. R. Meyer, by 10 a.m. Oct. 9.

Tenders are invited up to Nov. 22 for the supply of cable to the Postmaster-General's Department in QUEENSLAND; and up to Nov. 15 for the supply of telephone cords and earpieces to the Postmaster-General's Department in SOUTH AUSTRALIA. Tender forms, &c., from the Commonwealth Offices, 72, Victoria-street, London, S.W. See also advertisements.

Tenders are invited up to Dec. 20 for the supply of one branching multiple magneto switchboard at Broken Hill to the Postmaster-General's Department in NEW SOUTH WALES. Tender forms and specification from the Commonwealth Offices, 72, Victoria-street, London, S.W. See an advertisement.

Tenders are invited up to Nov. 21 for supply of one automatic or semi-automatic switchboard and equipment to the Postmaster-General's Department in WESTERN AUSTRALIA. Tender forms and specifications may be obtained at the Commonwealth Offices, 72, Victoria-street, London, S.W. See an advertisement.

LONDON County Council require tenders by 11 a.m. Oct. 24 for supply of hand-power overhead crane, h.t. and l.t. cables and switch gear, &c., rotary converters and static transformers, for sub-stations. Specifications, &c., from the Clerk.

HACKNEY (London) Borough Council require tenders by 7 p.m. Oct. 12, for supply of 100,000 pairs of white open type arc lamp carbons. Specification, &c., from the Town Clerk.

HASTINGS Guardians require tenders by Oct. 18 for the electric lighting of the workhouse premises, Ore, Hastings. Specification from Mr. S. Bumstead, 11, Wellington-sq., Hastings.

Digitized by Google

PERTH (N.B.) Corporation want tenders by Oct. 14 for coal storage hoppers, conveyors, capstans, electric generating plant for stoking machinery and extension of coal elevator and hoist. Specifications, &c., from the Gas Engineer.

CARLISLE Electricity Committee require tenders for water softening and purifying plant (4,000 gallons per hour) and a main l.t. feeder switchboard. Tenders to City Electrical Engineer by Oct. 14.

DUNDEE Council require tenders by Oct. 9 for material required in the erection of overhead tramway equipment at Clepington-rd. Specification, &c., from the City Electrical and Tramways Engineer.

Tenders are invited up to Oct. 18 for the supply of 20 coin-in-the-slot attachments to the Postmaster-General's Department in WESTERN AUSTRALIA; up to Oct. 25 for supply to the Postmaster-General's Department in SOUTH AUSTRALIA of cable and paper sleeves; up to Nov. 1 for the supply of 5,000 porcelain (No. 8) insulators to the Postmaster-General's Department in SOUTH AUSTRALIA; and up to Nov. 18 for the supply of ironwork, measuring instruments, switchboards, &c., to the Postmaster-General's Department, in QUEENSLAND. Tender forms, &c., from the Commonwealth Offices, 72, Victoria-street, London, S.W.

The Metropolitan Water and Sewerage Board, Albert-street, BRISBANE, Queensland, want tenders by noon Jan. 30 next for supply and erection of one, two or three complete units, each consisting of power generating plant and pump or pumps to lift not less than 6,000,000 gallons per day. Particulars from the Secretary, and forms from the Agent-General for Queensland.

DUNEDIN (N.Z.) Corporation require tenders by Nov. 1 for supply of (1) 500 B.H.P. vertical type gas engine or Diesel oil engine, suitable for rope driving an a.c. motor and d.c. generator; and (2) direct-coupled vertical type gas engine or Diesel oil engine and d.c. generator (800 kw. at 550 volts). Specification at 73, Basinghall-street, E.C.

TULCEA (Roumania) municipality require tenders by Nov. 19 for electric lighting of the town.

Tenders are invited by the Municipal Council of PELOTAS (Brazil) for a 40 years' concession for the supply of electricity for power and lighting and the establishment and working of electric tramways. Tenders to Senhor Luiz M. da S. Pennafiel, Intendencia Municipal, Pelotas, up to 1 p.m. Nov. 14. A deposit (about £300) is required with each tender, to be increased by the successful tenderer to 25,000 milreis (about £1,670). Further particulars (in Portuguese) can be seen by British contractors at 73, Basinghall-street, London, E.C.

Tenders are wanted by noon Nov. 22 for supply of motor generators, accumulators, main switchboard, cable, &c., to the South African Government Posts and Telegraphs Department, PRETORIA. Particulars from G.P.O., Johannesburg or Cape Town.

Tenders will be received until Nov. 28 at the Directoria Geral Ministerio de Viaçao e Obras Publicas, Rio de Janiero, for harbour works at JARAGUÁ (Alagoas State) (estimated to cost £780,000), including the supply of six movable 1½-ton electric cranes, a fixed 30-ton crane and an electric lighting installation. Particulars can be seen at 73, Basinghall-street, E.C.

PORT ELIZABETH (Cape Colony) Municipality require tenders by Oct. 19 for the supply of electric motors and starting switches. Particulars from the Town Clerk.

The Bulgarian Directorate-General of Posts, Telegraphs and Telephones, SOFIA, require tenders by Oct. 23 for supply of telegraph and telephone material. Specification (in Bulgarian) at 73, Basinghall-street, London, E.C.

PLEVNA (Bulgaria) Municipality require tenders by Nov. 17 (from firms who have carried out similar contracts) for electrically lighting the town. Deposit of £1,000 required. Specifications from the Municipal Offices on payment of £1.

SYSRAN (Russia) Town Council require tenders by Oct. 14 for the construction of an electric tramway and the equipment of electricity works.

TENDERS RECEIVED AND ACCEPTED.

The following tenders were received by Poplar (London) Council for (*a*) one overhead bunker and (*b*) one combined coal elevator and conveyor:—

New Conveyor Co. (*accepted*) (*a*) £1,188, (*b*) £699, 10s.; Tickle Bros. (*a*) £1,076, (*b*) £490; Ed. Bennis & Co. (*a*) £1,270, (*b*) £610; John Spencer, Ltd. (*a*) £1,212, (*b*) £865; Edgar Allen & Co. (*a*) £1,730, (*b*) £918; Barry, Hendry & Co. (*a*) £2,050, (*b*) £475; Babcock & Wilcox (*a*) £2,100, (*b*) £760; Dempster & Sons (*a*) £1,654, (*b*) 1,015. The specification of the lowest tender was incomplete and no drawings were submitted.

Launceston (Tasmania) were recently recommended by the Electricity Committee to accept the following tenders for plant to supplement the power now available at the electricity works: Australian Metal Co., turbo-alternator, condenser and switchgear, £3,480, with an addition of £258 for spare parts; Babcock & Wilcox, for boilers, £2,859; total, £6,597; and that the Australian Metal Co. be allowed six months and Babcock & Wilcox 18 weeks for delivery.

Poplar (London) Council recently received tenders for a 3,000 kw. turbine alternator and condenser. Twelve firms sent in tenders, and many of them submitted several alternative quotations for different types of alternators, condensers, &c. We give below the highest and lowest tender of each firm:—

Willans & Robinson (G.E.C. alt.) (*accepted*), £7,581; E.C.C. alt., £8,364. 14 tenders.

Richardsons, Westgarth & Co. (G.E.C. alt.), £7,522; Siemens alt., £9,375. 6 tenders.

Dick, Kerr & Co. (Mirrlees, Watson cond.), £7,617; Allen cond., £7,652. 3 tenders.

C. A. Parsons & Co. (B. West. alt.), £8,306; Parsons alt., £8,832. 21 tenders.

Bellis & Morcom (G.E.C. alt.), £8,456; Siemens alt., £8,877. 3 tenders.

Brush Co., £8,728 and £8,460.

British Westinghouse Co., £8,776 and £9,269.

Jas. Howden & Co. (B. West. alt. and Mirrlees, Watson cond.), £8,970; Vickers alt. and Mirrlees cond., £9,339. 12 tenders.

John Musgrave & Sons (G.E.C. alt.), £9,267; Siemens alt., £10,011. 3 tenders.

Fraser & Chalmers (G.E.C. alt. and Mirrlees cond.), £9,925; Vickers alt. and Worthington cond., £10,605. 18 tenders.

British Thomson-Houston Co. (Mirrlees cond.), £9,854 and £9,728.

Five firms submitted quotations for the condensers only, viz.: I. Storey & Son (£3,195), Cole, Marchent & Morley (£2,865 and £2,695), Mirrlees, Watson Co. (£3,200), Worthington Co. (£3,180 and £2,930), and W. H. Allen, Son & Co. (£3,069 and £2,543).

After analysis of the tenders by the borough electrical engineer (Mr. J. H. Bowden) the Electricity Committee recommended the acceptance of Messrs. Willans & Robinson's tender at £7,581.

Hackney (London) Guardians received tenders from six firms for the extension of the telephone systems at their buildings at Homerton. The quotations varied from £252. 10s. (by the Private Telephone Co.) to £672. 10s. (by the British Home & Office Telephone Co.), and the lowest tender has been accepted.

Wigan Council have accepted the tender of the Rees Roturbo Co. (at £261) for supply and erection of two electrically-driven centrifugal pumps for the water department.

Rugby Council have accepted the tender of the British Thomson-Houston Co. for three transformers.

Swindon Guardians have accepted the tender of Rye & Co. for cotton-covered electric cable at 1¼d. and 1⅝d. per yard, and flexible electric cord at 1½d. per yard.

Bermondsey (London) Council have accepted the tender of S. Pontifex & Co. for supply of 50 electric street lanterns at £48.

The tender of the Automatic Electric Co. (Sydney) has been accepted for the installation of the automatic telephone system at Geelong (Victoria).

Southwark Council have accepted the tender of the British Insulated & Helsby Cables, at £231. 15s., for supply of 440 yds. of 0·3 l.t. t.c. cable, and, (at £40), for an eight-way feeder pillar.

Haslingden Council have placed an order with Ferranti Limited for a switchboard, and with the British Westinghouse Co. for station transformers.

Eccles Council has accepted the tender of Ferranti Limited (at £709) for supply of a h.t. single-phase switchboard.

Plant for Sale.—Mr. F. Lake, 132, Upper Thames-street, London, E.C., advertises for sale electrical sundries, cables, lamps, instruments, &c.

Agency.—A German firm of accumulator manufacturers advertise for a London firm with a connection among motor-car makers, &c., to take over the sole agency of their portable accumulators.

Business for Sale.—The business of an electric motor manufacturing company is advertised for sale in another column.

Patents Development.—The proprietor of patent No. 2,181/1905 for "Improvements relating to electric measuring instruments," desires to make arrangements for exploiting same in this country. Applications to Messrs. Haseltine, Lake & Co., patent agents, 7 and 8, Southampton Buildings, Chancery-lane, London, W.C.

The owners of British patent No. 23,778/1907, for "Improvements in the manufacture of electric resistances," desire to sell their patent rights or to grant licences thereunder. Particulars from Messrs. Day, Davies & Hunt, patent agents, 321, High Holborn, London, W.C.

The proprietor of British patent No. 20,746/1908, for "Lamp shades, globes and reflectors," desires to enter into arrangements

Digitized by Google

with British manufacturers with a view to the exploitation of same. Further particulars from Mr. H. Skerrett, chartered patent agent, 24, Temple-row, Birmingham.

BUSINESS NOTICES.

The North Western Electrical Appliance Co., formerly of Catheart, Glasgow, have removed their works and offices to Railway Appliance Works, Darlington.

Arthur Paxton and Sydney C. Fifast, electrical engineers and electric supply merchants, Fynyeod-street, Cardiff, have dissolved partnership. Debts by Mr. Paxton, who continues.

BANKRUPTCIES, LIQUIDATIONS, &c.

An application for the discharge of Joseph A. Bauer (trading as the Electrical & General Engineering Co.), 17, Gracechurch-street, London, E.C., will be heard on Oct. 25 at Bankruptcy-buildings, London, W.C.

A meeting to receive an account of the winding-up of Havana Telephone Securities Co. (Ltd.) will be held on Oct. 31 at New Broad-street House, London, E.C.

The Winchester Electric Light & Power Co. (Ltd.) is being wound up voluntarily. Messrs. F. E. Gripper and A. R. Dyer are liquidators.

COMPANIES' MEETINGS AND REPORTS.

Direct United States Cable Co. (Ltd.)

The sixty-eighth ordinary general meeting was held on Friday last, under the presidency of Mr. E. M. UNDERDOWN, K.C.

The SECRETARY (Mr. W. Miles) read the notice convening the meeting and the auditors' report.

The CHAIRMAN said: In view of the meeting that is to follow, I do not propose to detain you long. The outstanding feature in the accounts for the past half-year is the decrease of £12,326 in revenue, due to the Western Union Co. having ceased, since March 1 last, to hand over to us or to the Anglo Co. the proportion of the eastward traffic that up to that time, since the year 1882, had always been dealt with by us. The increase of £2,471 in the working expenses is entirely due to the establishment of the Harbour Grace station consequent upon the diversion of the cable to Newfoundland, which, as I have previously informed you, has resulted in an acceleration of the speed at which messages are transmitted over the cable, equal to 70 per cent. upon its previous speed. I do not propose now to refer to the provisional agreement with the Western Union Telegraph Co. that we have entered into, as the proposal before you is simply to adopt the Directors' report and accounts. The reason for the delay in the issue thereof is explained in the report. In the middle of July, when the accounts have usually been circulated, we were entering upon the final stage of the protracted negotiations that have resulted in the agreement, and we thought it undesirable to publish the accounts at that time. Those negotiations have now been brought to a conclusion, and, as you will see, if the agreement is approved by you, the Western Union Co. will be required to hand us a sum of £10,800 in respect of the traffic withheld since March 1, to which I have previously referred, so that the diminution in our revenue will be practically covered. Some explanation may be looked for as to the payment of a dividend of 2s. and a bonus of 1s. for the quarter to June 30 last. It was, from a diplomatic point of view, desirable to maintain the usual rate of dividend for the final quarter of the year, and looking to the fact that our reserve fund stood at a sum well over £500,000, which had been deemed a sufficient amount to provide for the replacement of the cable should that be necessary, while it had been increased during the year by some £18,000, we considered ourselves justified in using some £7,000 of that increase of £18,000 in paying a bonus to the shareholders. I may also add that your Directors were fully alive to the strength of the position of our undertaking, and were confident that the Western Union Co. would concede terms that would be regarded as satisfactory by the shareholders. I appeal very confidently for your approval of what we have done, and move the adoption of the report and accounts.

Sir JAMES PENDER, Bart., seconded the motion, which was carried unanimously.

The retiring directors (Mr. E. M. Underdown and Mr. H. C. B. Underdown) and the retiring auditors were then re-elected. This terminated the proceedings of the ordinary general meeting.

An extraordinary meeting followed, when the heads of the agreement with the Western Union Co. were read by the Solicitor (Mr. T. G. Cowan, of Messrs. Slaughter & May).

The SECRETARY then read the resolutions to be put before the meeting, which expressed acceptance of the agreement by the shareholders of the Company, and effected the necessary alterations in the Articles of Association.

The CHAIRMAN, in proposing the adoption of the resolutions, said: You have doubtless all received a copy of the Secretary's communication of Sept. 15 giving in a summarised form particulars of the more salient provisions embodied in the provisional agreement for leasing the cables of this Company to the Western Union Co., and this your Directors recommend you to-day to adopt. In proposing the resolutions that have just been read I will relate the circumstances which have necessitated our entering into this proposed agreement and our reasons for recommending you to approve of our action so far, and formally to sanction the arrangement by your vote. You are probably all aware that since the year 1882 this Company has been working with the Anglo-American Telegraph Co. and the Western Union Telegraph Co. under agreements entered into with a view not only to secure and maintain the successful carrying on of this Company's cable business, but also to give to the public an efficient cable service between this country and the United States and Canada founded upon the mutual support and facilities existing between the cables for all purposes, it being conceded that there is a necessity for a fair number of lines across the Atlantic if steady communication is to be secured. Under that arrangement the bulk of the cable business was, up to 1882, conducted over the cables of the Anglo- and Direct Companies. The Anglo possessing four cables to our one, it will be obvious to you that the proportion of traffic dealt with by us was small as compared with that dealt with by the Anglo Co. In 1882 the Western Union Co. joined the combination with two cables, while the land lines and communications on the other side were conducted by the Western Union. In order that you may properly appreciate the position of the Western Union Co. in America I must explain that it is a company possessing, in addition to cables across the Atlantic, an independent telegraph system, in many respects comparable with that of the telegraph system in this country, which, as you are aware, is now in the hands of the Government. The Western Union Co. has not, indeed, a monopoly of the telegraph system in America, but its only serious competitor is the Postal Telegraph Co., an ally of the Commercial Cable Co. The Western Union Co. is, without doubt, in a predominant position as regards telegraphic communication in the United States, the postal system being a less extensive one. In the year 1910 the Western Union Co. had 24,825 offices in the United States, operating 1,429,049 miles of wire, and 214,360 miles of poles and cables. The total receipts of the Western Union Co. for the year 1910 amounted to the huge sum of $33,889,202, equal to nearly £7,000,000, and after paying all expenses, interest, and dividends for the year, a balance of revenue remained of $2,597,373, or over £500,000. These figures will give you some idea of the magnitude of the Western Union Co.'s operations, and I have no doubt will satisfy you that the payment of the rental for our cables is well secured by the undertaking of that company. Although the Anglo and Direct companies have hitherto maintained separate offices in New York and other centres, under the working arrangement that existed between the three companies, the Western Union Co. acted in America, to all intents and purposes, as collectors of cable messages passing over the cables of the three companies, and these messages were distributed and dealt with in agreed proportions. In the early part of 1910 a controlling interest in the Western Union Co. was obtained by the American Telegraph & Telephone Co., and a change in the management of the former company followed. About the same time the Government of the United States proceeded to put in force an Act of Congress known as the "The Sherman Anti-Trust Act," which prohibited combinations characterised as being in restraint of trade, and in view of this the Western Union Co. was advised that the agreement then existing between that company and the two English companies involved a contravention of the Sherman Act, and that the only method of avoiding it was to enter into some fresh agreement which would do away with the objectionable features of the combination. In May, 1910, negotiations were commenced with the Anglo and Direct companies to this end, and certain proposals were then submitted to us which we were reluctantly compelled, in your interests, to decline. So far as this Company was concerned, this was the position of matters when, in February last, the Western Union Co. gave notice that, in view of the agreement being considered as a violation of the provisions of the Sherman Act (and the Directors and officials of that company feared they would, in the event of the Government taking action, incur penalties of a severe kind), after March 1, 1911, the agreement that had been in existence between the three companies since 1882 would no longer be recognised. Your Directors meanwhile had obtained the highest legal advice in America and on this side, and it was at once intimated to the Western Union Co. that this Company could not accept that notice, and that we adhered to and held them, to the 1882 agreement. The Western Union Co. therefore gave notice cancelling the convention of 1882. The advisers of the Western Union Co., who, after all, are the people chiefly interested, are satisfied that the proposed lease is not a contravention of the Act. It must be admitted that our own advisers were not so confident, while an American counsel, consulted by the Anglo Co., has expressed the view that while it is not possible to pronounce with certainty upon the validity of the agreement, in his opinion the proposed lease is good under American common law, and would not be held to be in violation of the Anti-Trust law. We have, therefore (although a recent judgment of the Supreme Court has considerably modified the views of the Government as to the effect of the Sherman Act, and a statement has been made with authority that the United States authorities would be prepared to take all circumstances into consideration in connection with these matters), had to bear in mind the possibility that the proposed lease might be regarded as within the meaning of the Sherman Act. This aspect of the question has, you may be sure, been most closely and carefully considered by your Directors, and, while they appreciate that there is a risk, it is believed to be a distant one. With full knowledge of the position we have taken every step to effectually safeguard your interests and ensure that, even should the lease be broken, or even, which is quite possible, modified with our consent, you will be certainly in no worse position, than you were when the Western Union Co. repudiated the 1882 agreement. Then, on March 1 last, the Western Union ceased to hand over either to us or to the Anglo Co. any portion of the Eastward traffic collected by them on the other side. This represented nearly 50 per

Digitized by Google

cent. of the messages transmitted over the cables. That statement will make clear to you the enormous loss that resulted to the English companies. This, put into figures, brought about a reduction in our revenue for the four months to June 30 last from £42,500 to £28,290 as compared with the corresponding four months in 1910, or a decrease of £14,210, and this on the assumption that our original agreement with the Anglo Co., entered into in 1877, prior to the admission of the Western Union Co., would still have held good, and that we should receive our full proportion of the traffic of the two companies, Anglo and Direct, as provided under that agreement. In the intervening months we were from time to time informed that negotiations were proceeding between the Anglo and Western Union companies, and it was intimated to us that when these were contemplated the Western Union Co. would approach us with a view to entering into a similar arrangement. In the early part of July we were informed that these two companies had come to an agreement, and the Western Union Co. then approached us. This was the position in the month of July, when it had been usual to issue our half-yearly accounts and to hold the annual meeting, and, as I informed you just now, we considered that in the circumstances that was not a suitable time for calling you together. Now, you may doubtless be disposed to ask me whether the arrangement before you might be broken by one of the parties or is or is not capable of being held invalid for the above-mentioned reasons, and whether, if so, the existence of the proposed contract might be endangered. I think we may look upon this in the light of the attitude and intention of the parties, and especially of the Western Union Co. I am convinced that the latter company will loyally endeavour to substantially uphold this agreement, even should legal necessity require some modification not of a vital character. It is clear that both parties will endeavour to exclude anything of an illegal nature. Our negotiations with the Western Union Co. have resulted in the arrangement which has been communicated to you and which your Directors recommend you to accept. We carefully studied the possible alternatives—namely (1), to revert to the original 1877 agreement with the Anglo Co.; (2), to endeavour to work alone. The latter alternative seemed an impossible one, seeing that we have only one cable across the Atlantic, and that interruption thereto would result in complete cessation of revenue; while as regards the other alternative, we have had four months' working with the Anglo Co. (without the Eastern traffic coming from the Western Union Co.'s system), and the result has conclusively demonstrated that our receipts under the 1877 agreement would probably have been little more than sufficient to meet our working expenses. Again, the question might be asked whether the two English companies could not have combined and established their own land line connections in America. I can only say that the institution of any such system by the English companies would have been a most costly undertaking, beset with such difficulties including the strenuous opposition of existing telegraph companies in America, as to make it practically impossible of accomplishment, at any rate with the capital at the disposal of the English companies. I am bound to state that the Anglo Co. proceeded with their negotiations and came to their agreement without consulting your Directors in any way thereon, and we had therefore to take care of ourselves. I now hear that the arrangement between that company and the Western Union Co. has been unanimously approved to-day at the extraordinary general meeting of the Anglo Co. That agreement is not identical with our agreement, but, of course, it is analagous to it. The assent to the agreement as between us and the Western Union Co. is not governed by that agreement, but it is satisfactory that it has been approved, as it shows that these great companies will all act together practically under the same regulations and conditions. It was, however, obvious that we could not count upon the co-operation of that company in attempting to provide our own means of communication between the cable ends and the interior of America. As I said just now, the only course open to us was to come to the best arrangement possible with the Western Union Co., and I have no hesitation in saying that we have, after many months of anxious negotiation, succeeded in doing this and have secured terms which we can honestly recommend for your acceptance.

Mr. UNDERDOWN proceeded to refer to the chief points of the new agreement and to the old arrangements which the agreement displaces. Their old cables were, he said, working admirably. The arrangements to limit the dividend to 4 per cent. was quite as much in the Direct Company's interest as in that of the Western Union, as it ensured that any balance remaining out of the interest of the reserve fund, after paying for repairs to the cable, would be added to the reserve fund, so that if a new cable should be required the Direct Company would have the means to purchase it. The policy of the Board in the future would be to pay quarterly dividends, as hitherto, at the rate of 4 per cent., to take into account the expenditure upon repairs and renewals of the cable, and to declare or not to declare the bonus as the circumstances warranted. The whole of the Company's staff, with the exception of the secretary and his assistants, who naturally remained with the Direct Company, are to enter the services of the Western Union Company under all the conditions of their present employment, and the Western Union Company undertakes to contribute an annual sum sufficient to maintain the pension scheme for the entire staff. The Postmaster-General, he understood, had stipulated that the stations of the English companies should be staffed by British subjects. Everything had, therefore, been done for the staff, of whose loyalty and devotion to duty the Directors desired to express their warm appreciation. He then proposed the adoption of the resolution assenting to the terms of the arrangement with the Western Union Company.

Sir JAMES PENDER seconded.

In reply to questions, the CHAIRMAN said that each company, the Anglo and the Direct, made their own agreements, and these agreements did not stand or fall together in any way. The arrangements of the old so-called "pool" disappeared altogether. With regard to the operation of the Sherman Act, should any difficulty arise they were in no worse position than they would be otherwise. They had their reserve fund, their interest upon this, their property, and their goodwill for what it might be worth. They had given up nothing but whatever rights they might have under the 1882 agreement. Under the new arrangement they not only retained their own property, but they had rights over the Western Union Company's land lines in the United States. The Chairman then asked for a show of hands, and declared the resolution carried unanimously.

The amendments to the Articles of Association were then approved, and a vote of thanks to the Chairman and Directors was agreed to with acclamation.

The CHAIRMAN, in reply, expressed the thanks of the Board to the officials of the Company for the assistance they had rendered, and said the shareholders were much indebted to the Secretary for the manner in which he had conducted the negotiations.

The proceedings then terminated.

Anglo-American Telegraph Co. (Ltd.)

An extraordinary general meeting of this company was held on Friday last, under the presidency of Mr. F. A. BEVAN, for the purpose of passing three resolutions: (1) approving the conditional agreement dated Aug. 22, 1911, between the company and the Western Union Telegraph Co., and authorising the directors to carry the agreement into effect in due course, subject to such modifications (if any) as they may from time to time approve; (2) altering the provisions of the memorandum of association of the company; and (3) providing that, upon the conditional agreement becoming operative and any present directors retiring within three calendar months after it becomes operative, there be paid out of the funds of the company to the said directors so retiring £4,000, to be divided amongst such retiring directors as they may agree.

The SECRETARY (Mr. T. H. Wells) having read the notice convening the meeting,

The CHAIRMAN proposed the resolutions. He said the circular which had been sent to the stockholders embodied all the principal points of the provisional agreement with the Western Union Co. He need hardly say that the proposal came from the other side. The Anglo-American Co. would have been quite satisfied to continue to work under the pooling agreement between themselves, the Direct United States Co., and the Western Union Co., but those who had the management of the Western Union Co. were of opinion that if the three companies could be brought under one management it would be easier to effect improvements which they had in contemplation in working the cables and to save expenses. With that object the negotiations for the agreement were commenced, and when they had made considerable progress the Western Union Co. discovered that the pooling agreement under which they had been working so satisfactorily, as far as the Anglo-American Co. was concerned, for many years, was in contravention of the Sherman Anti-Trust Act. In this country we were no judges of what that Act was, and therefore the directors had thought it right to consult the best legal opinion they could obtain on the other side, and they invited over here one of the most eminent lawyers in the United States, a gentleman of remarkable acumen and experience, and the directors had every reason to think that the advice he gave them was thoroughly sound. He told them that the matter could not be absolutely settled without going to a court of law, but he had no doubt that if it were brought to the notice of a court of law they would declare the pooling agreement to be illegal. Whether they would have done better to go into a legal fight, which would have taken a long time and cost a good deal of money—and during the time the contest lasted the stockholders would have received considerably less—he could not say, but the directors thought that the better way was to assume that the advice they had received was correct. The Western Union Co. at once stated that, believing the advice to be correct, they would terminate the pooling agreement as from March 1 last, which meant that instead of the earnings being divided, as before, in certain proportions between the three companies, each company would do its best to get traffic and would be entitled to the earnings it made. Therefore, whether they got more or less depended upon their own unaided work—a totally different matter from having the traffic pooled as hitherto. It must also be borne in mind that there was a slight, although not more than slight, advantage to the Americans as compared with themselves—that was to say, that the traffic from America was rather larger than the traffic to America. In addition to that, the Western Union Co. had enormous inland business on the other side, and it was only natural that they would be able to get hold of the traffic on their side in a way the Anglo Co. could not possibly do, having only their own line on this side. In the directors' opinion those were strong additional reasons why they should enter into the agreement. What might have been the issue had they gone into a fight he could not say, but the directors were of opinion that under the proposed agreement the company would be much safer than if they had gone into a regular stand-up fight with their former colleagues and friends.

Those were the principal reasons why the directors had thought fit to submit the agreement to the stockholders, and why they strongly advised the stockholders to approve it. The stockholders knew what the principal points of the agreement were. It was a lease for 99 years, and it guaranteed 3¾ per cent. on their ordinary stock, which meant 6 per cent. on the preferred and 1½ per cent. on the deferred—an amount which they had only once exceeded since 1884—that was, since they had had the present tariff. If they took that 3¾ per cent. on £7,000,000, it seemed to him that it was a very good return, because if they looked at the

Digitized by Google

market price of their stock, it was something like £4,500,000—rather over. Therefore 3¾ per cent. on £7,000,000 represented a much higher rate of interest than 3¾ per cent. on the market price of the stock. Besides that the Western Union Co. had to maintain this company's cables and plant. They had also to keep up the Anglo Co.'s renewal fund until it reached £1,000,000, just as it was under the previous arrangement; and they took over all this company's liabilities and relieved them of the management of the cables. On the other hand, the Anglo Co. had to purchase from the Western Union Co. the cable which the latter laid a few months ago. The amount would come out of the renewal fund, which would thus be diminished by a very large amount, and the Western Union Co. would have to continue adding to the fund a considerable sum in order to make it up to £1,000,000. The Western Union Co. were bound under the agreement to maintain five cables, but in the case of the failure of two of the old Anglo cables they could substitute a new cable equal in power to the two old ones, and then they would have to maintain four cables, including the one to be purchased from them by the Anglo Co. There were never to be fewer than four cables, and the Anglo Co.'s plant was to be maintained and their dividend to be secured, whatever happened. There were certain contingencies under which the lease might terminate. If the Western Union Co. were to fail in paying the guaranteed dividend the Anglo Co. could give them notice to terminate the contract. On the other hand, if by the action of either the British or the United States Government it was found practically impossible to carry on the traffic, then the Western Union Co. would be released from their obligations. It appeared to him, however, that those contingencies were most unlikely when they thought of the magnitude of the Western Union Co. and its earning powers. Over and above the dividend it paid there remained a very large amount. He also thought, taking into account that the traffic itself, from natural causes, was likely to increase, that their 3¾ per cent. was about as safe as it was possible to be, and that, in fact, instead of having, as the deferred stockholders had, what he might call a speculative stock, judging by the fluctuations in its price, they would have really a gilt-edged stock, which would not be subject to such fluctuations. He saw that it had been hinted in the newspapers that some difficulties might occur. It had been suggested that the new agreement was a violation of the Sherman Anti-Trust Act. He need not tell the stockholders that the directors had taken counsel's opinion on the point, and they were assured that, as far as they could tell, the agreement was not in violation of that Act. It seemed to him that there was this difference, that instead of there being, as now, a combination of three companies to maintain certain rates—for neither of them could alter the rates without the consent of the others—it was now in the power of the Western Union Co. to vary their rates as they pleased without consulting the Anglo Co. or the Direct Co. They could put the rate up or down so far as the Anglo Co. was concerned, but they would have to pay the latter 3¾ per cent., whatever the rate might be. It was difficult to prophesy, but as far as he could foresee there was no reason why the agreement should not last. He desired to say, in conclusion, that if from any unforeseen cause the agreement came to an end, the position of the Anglo-American Co. would be that they would resume their five cables in certain contingencies or four cables as a minimum, they would have all their plant that was not perishable handed back to them, they would have their renewal fund at whatever amount it might have reached, and, in addition, they would have the assurance, as would be found by an article in the agreement, that the Western Union Co. would do their utmost to restore them, as far as traffic was concerned, to the position which they occupied in the year 1910. He thought the stockholders would agree with him that the directors had in every way possible guarded the interests of the company, and in asking them to pass the resolutions the board believed that they were doing that which was best and safest for the interests of the stockholders.

Sir GERALD FITZGERALD seconded the motion.

The MANAGER (Mr. J. H. Carson), in answer to Mr. CHESTER, said the traffic was nearly divided equally between east and west; about 52 per cent. from America and 48 per cent. from this side.

The CHAIRMAN, in reply to other questions, said that, in exchanging their money for a new cable the Anglo Co. were not in any way damaging themselves. They were getting a very fine new cable, and they would in any case have had to lay a new cable a few years hence. What was the position under the agreement? They would have five cables to the Western Union Co.'s two, and the cables were the property of the Anglo Co., not of the Western Union, to whom they were only leased. Therefore, in the event of the agreement breaking down, they would be in a very much better position having the cable already laid, even than if they had the money instead. They had the 1873 and the 1874 cables, and they had had considerable trouble with one of them lately, and if they had not come to the proposed agreement with the Western Union Co., it would probably have been prudent for them, in the next two or three years possibly, to have laid a new cable. The Western Union Co. did not disclose what their reserve fund was, but they kept what they called a surplus account which last year amounted to $2,597,000. They always carried forward a very large surplus and did not divide at all closely. Their net revenue last year was $7,274,900, whereas a few years ago it was $5,700,000. Their capital stock issued was close upon $100,000,000 (£20,000,000).

The SOLICITOR (Mr. Carslake), in reply to a stockholder, said the contract was an English contract, and they could therefore sue the Western Union Co. here as well as in America. They could get judgment against them here and put in a receiver of all the receipts on this side. Again, if they broke the contract the Anglo-American Co. could determine the lease and resume possession of their property. With respect to the position if the Sherman Anti-Trust Act were put into force and the lease were declared invalid, the company would again have all their cables back; and the lease contained a provision that the Western Union Co. were in that event to give the Anglo Co. the same facilities in the United States for the transmission of their traffic over the land-lines which they enjoyed up to the end of 1910. The new cable would belong absolutely to the Anglo Co.; it would only be leased to the Western Union.

The CHAIRMAN then put the resolutions to the meeting, and declared them carried unanimously.

A vote of thanks to the chairman and directors terminated the proceedings.

DRAKE & GORHAM (LTD.)—The directors' report for the year ended June 30 states that, after payment of all charges, including bonuses due to staff, there remains a nett profit of £7,184. 7s. 6d., added to £1,242 4s. 9d. brought forward. Dividend of 4½ per cent. requires £5,625 and £1,500 is written off underwriting commission, leaving £1,301. 12s. 3d. to be carried forward. The improved results are mainly due to the increasing popularity of the electric light, especially in view of the large reduction in first cost and running expenses. The wholesale department has been further extended and an additional warehouse will shortly be ready for occupation.

WESTERN UNION TELEGRAPH CO.—The report of this company for the quarter ended Sept. 30 states that there was a surplus at March 31 of $9,313,702.36, and net revenue for the quarter ended June 30 was $1,982,493.17. After appropriating $747,886.50 for ¾ per cent. dividend paid July 15, and $433,953.05 for interest on bonded debt, there was a surplus at June 30 of $10,114,355.98. Net revenue of the quarter ended Sept. 30, based upon completed returns for July, partial returns for August and estimating the business for September, will be about $2,220,200.00, interest on bonded debt will require $434,062.00, and dividend of ¾ per cent. $747,887.00, leaving a surplus of $11,152,606.98.

WILLANS & ROBINSON (LTD.)—The directors' report for the half-year ended June 30 states that after writing off £4,428. 12s. 9d. depreciation, paying £4,173. 18s. 5d. interest on debenture stock and £348. 9s. 7d., the cost of the upkeep of the Queen's Ferry works, the result of the half-year's trading shows a loss of £7,692. 14s. 7d., compared with £10,811. 3s. for the previous six months. Added to the balance £26,079. 19s. 9d. brought forward from the previous half-year, this brings up the total of the debit standing against profit and loss account to £33,772. 14s. 4d. Although the company is securing its fair share of orders, the prices obtainable, due to the continued excessive competition, render these largely unremunerative. The company's area of operations is being judiciously extended. The economies referred to at the last half-yearly meeting, and which are only partially operative in the current balance-sheet, should materially assist in meeting the severe conditions at present existing. The regrettable lawsuit (referred to at previous meetings), involving a claim for £10,000 damages, has now been concluded, a verdict of £3,411 damages (with costs) being given against the company. The total cost to the company of the action amounts to £23,519. 8s. 11d. Provision against this liability to the extent of £3,863. 8s. 2d. has already been made, leaving £19,656. 0s. 9d. still to be dealt with. The matter concludes the liabilities arising out of the Queen's Ferry works, prior to their being closed in 1908, and is in no way attributable to the business carried on at Rugby.

CITY NOTES.

MEMORANDA (Oct. 5).—**Bank rate 4 per cent.** (since Sept. 21, 1911). Price of silver, 24¼d. per oz. **Consols** 77¼—77½ for money, 77¼—77⅝ for account. **Consols Pay Day**, Nov. 3; Stock and **Shares Continuation** Days, Oct. 19 and 25; **Ticket Days**, Oct. 11 and 26; **Pay Days**, Oct. 12 and 27; **Mining Shares Carry Over** Days, Oct. 9 and 24.

PRICES OF METALS (London).—*Copper*, cash, 54½; three months, 55. *Lead*, English, 15⅞—15½; Foreign, 15⅛—15¼. *Spelter*, 27½—27. *Tin*, English, 190—192; Foreign, cash, 183; three months, 183. *Iron*, Cleveland, cash, 46/9½, three months, 47/4.

ANGLO-AMERICAN TELEGRAPH CO. (LTD.)—The board of directors have resolved to declare an interim dividend for the quarter ended Sept. 30 of 15s. per cent. on the ordinary stock and £1. 10s. per cent. on the preferred stock (less tax) payable Nov. 1.

CALCUTTA TRAMWAYS CO. (LTD.)—An interim dividend of 2s. 3d. per share has been declared on the ordinary shares (at the rate of 5 per cent. per annum, tax free), on account of the year to Dec. 31 next.

FOLKESTONE ELECTRICITY SUPPLY CO. (LTD.)—The directors have declared an interim dividend at the rare of 6 per cent. (3s. per share) less tax, on the ordinary shares for the half-year to June 30.

LISBON ELECTRIC TRAMWAYS (LTD.)—The directors have declared an interim dividend of 3 per cent. (tax free) on account of current year.

SUBMARINE CABLES TRUST.—Notice is given that on the 16th inst. the coupon due on that date will be paid by Messrs. Glyn, Mills & Co. Coupons should be left four clear days before payment.

WINCHESTER ELECTRIC LIGHT & POWER CO. (LTD.)—At an extraordinary meeting last week it was resolved to wind up the company voluntarily; and Mr. F. E. Gripper (Broad Sanctuary Chambers, Westminster) and A. R. Dyer (Palm Hall, Winchester) were appointed liquidators.

THE ELECTRICIAN COMMERCIAL AND INDUSTRIAL SUPPLEMENT.

C. & I. Supplement No. 80.] APRIL 14, 1911. [Gratis to Subscribers.

STANDARDS IN TRADE LITERATURE.

We recently received some leaflets from the Engineers Standardized Publications which remind us of the movement now being made to bring manufacturers into line in the size and style of certain of their literature. As far as we are aware, nothing has been done to include complete catalogues—bound trade volumes so to speak—in this new scheme of standardization. There are, naturally, difficulties in the way of any such attempt. The only arrangement approaching to standardization is that in which a very large number of loose leaflets are held together in a file; also all these sheets can be of uniform size, and the file will conveniently hold a hundred or so of them.

Some manufacturers who are now inseparable from the card index system and have adopted loose leaf ledgers, &c., will not object to the building up of a catalogue of loose leaves in an imposing file. On the other hand the majority, representing probably 75 per cent. of the total, are averse to adopting any such suggestion. When the subject is looked into in the most cursory manner by those who handle big budgets of trade literature, as we ourselves do, the first impression gained is that a maker's catalogue is something in which he takes a peculiar pride. The catalogue is an index of the *personnel* and management of a trade or industrial organisation. The larger the concern the more imposing as a rule is its trade literature. The heads of departments usually decide the contents of the particular piece of literature, and the directors select the quality and colour of the binding, the result is a reflection of the particular ideas of the management of what a good list (in their opinion, of course) should be. In other words the compilation and general appearance of the catalogue are as much to the company as the education of a traveller in the selling of their goods. In many instances the production of a new catalogue gives genuine pleasure and satisfaction to the staff. We have on our trade bookshelf volumes, brochures and booklets which we were delighted to receive; the sight of the cover, gold embossed or emblazoned, maybe in colours, sent a thrill through us as we carefully turned back the tissue paper in which they were wrapped. We were also overwhelmed with longing to have a quiet half-hour to go carefully through the contents. The object of the manufacturer with the production of such a list is achieved many times over when such feelings are aroused in the recipient of his literature.

It is just here that the literature standardising specialist will find his difficulty. The average manufacturer is not attracted to the loose leaflet and file idea for his main catalogue, no matter how imposing the cover of the file is made. He gets so accustomed to compiling his ponderous trade tome at stated intervals that it appears little short of sacrilege for him to do the work on the "unit" system, building up slowly or quickly, as the case may be, a page or a few pages at a time.

And in great measure he is not to blame. Specialist businesses almost compel uniformity in trade literature, but even with them the desire to standardise in everything but the main catalogue is very strong. We think that as long as manufacturers must appeal to the buyer through the medium of the printed page they will retain the right to handle their literature in their own way.

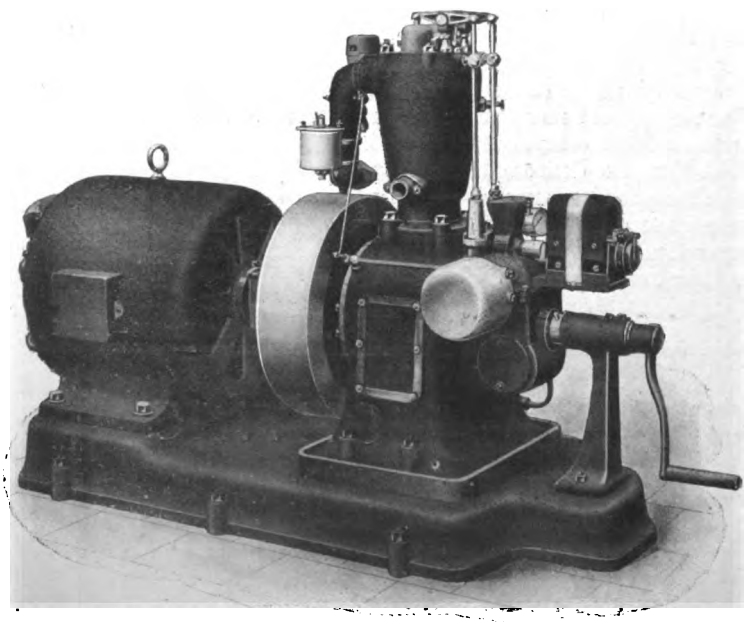
PRIVATE LIGHTING PLANT.

The petrol paraffin high speed vertical engine has been developed considerably during the past few years by makers of motor car and motor boat engines. The experience in the



BOULTON & PAUL PETROL DYNAMO SET.

manufacture of internal combustion engines which firms of this class derived from their motor car work must be of exceptional value in dealing with small engines intended for stationery work, and for direct coupling to dynamo electric machines. Messrs. Boulton & Paul, Norwich, are well known in the industry as makers of motor boat equipments, and we notice in their latest catalogue of marine motors that they include a special section on petrol paraffin engines intended for country house lighting plants or for direct coupling to centrifugal pumps, and similar high speed machinery. The list contains descriptions of several types of plant, and we understand that the company is prepared to supply complete electric lighting equipments comprising the engine and generator, accumulators and main switchboard. The engines are made to operate either on the Otto cycle or 2-cycle principle. In each case they are watercooled. The 2-cycle engine has the advantage of operating with a minimum of moving and wearing parts. There are no valves, springs or gears. The construction employed is fairly well known, the crank case being utilised as a compression chamber. Air and gas are drawn into the crank case on the upward stroke of the piston, and on the down stroke this mixture is slightly compressed. There are ports in the cylinder walls, and at the bottom stroke of the piston the inlet port is opened and the mixture is then forced up into the compression space by the rising piston. The charge is exploded, and at the extreme limit of the outward stroke the exhaust portion of the cylinder wall is uncovered. The gases pass out into a water-jacketed expansion box, into which a continuous spray of water is passed. This moisture reduces the temperature and pressure of the exhaust, and the gases pass away into the atmosphere in the form of steam at the pressure only slightly above atmosphere. This cycle of operations is repeated with the continuous rotation of the engine.

The use of a two-stroke engine for country house lighting or isolated plant of any description where the supply of skilled labour is naturally limited, will be appreciated by users of this class of plant.

The ignition in these engines is by high-tension magneto as a standard fitment, but coil and battery ignition can be fitted if desired. The governing is done on the throttle, and the speed can be adjusted while the engine is running. A feature of the catalogue in question is the listing of complete generating sets with battery and switchboard for the supply of 16 c.p. lamps, varying in number from 50 to 600. The price of the 50 16 c.p. equipment for operating at 25 volts is £95, or for 50 volts £105. This appears to be extremely moderate, and is for the Otto cycle engine. For the two-stroke engine the equipment is priced at £70. The catalogue contains a quantity of useful information regarding the application of these engines to various industrial purposes.

ELLIOTT MICROMETERS.

Interchangeability is now the accepted order of things in most engineering products, consequently it is necessary to employ accurate gauges to check off both small and large work. For small pieces the hand micrometer gauge is commonly used, and it is now obtainable in extremely accurate patterns. Hitherto the call was mainly upon foreign makers of these gauges because the British manufacturer had not stirred himself sufficiently to produce anything of the kind. Messrs. Elliott Bros. who are well known as makers of electrical instruments have now on the market a line of micrometer gauges which they are anxious to bring to the notice of British users of such devices, as an absolutely indigenous product. After considerable experiment and experience in the construction of tools and appliances, they have produced a micrometer which they claim can compete successfully with foreign patterns, both on the score of accuracy

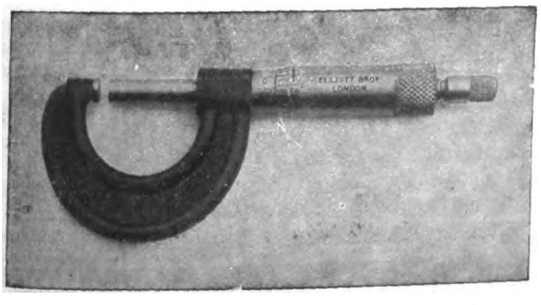
standard screws from which the micrometer threads are originated. These standards were brought into agreement with those at the Laboratory.



1 IN. ELLIOTT MICROMETER.

A special arrangement has been adopted for the figures round the measuring head, so that each division is numbered and can be easily read. The longitudinal scale on the frame is also provided with long and short lines, enabling the intermediate divisions between the numbers to be clearly distinguished.

From a brochure just brought to our notice we gather that 1 in. and 2 in. patterns of micrometer are offered, there being two styles of each pattern. Readings are in thousandths of an inch, and there are adjustments for taking up wear in the measuring screw, and also for adjusting the zero. Numerous handy accessories are also provided for making the micrometer more convenient to use.

ELECTRIC CHARGING MACHINE.

Messrs. Babcock & Wilcox recently received an order for a charging machine from Messrs. Steel, Peech & Tozer, Sheffield. The machine is of the low ground type, and is electrically-driven by four separately controlled motors. The machine picks up the charging boxes and carried the contents into the hearth of the open hearth furnaces in the usual way. It would deal with a load of 3 tons in the charging box. The machine is arranged upon the makers' special design, several

improvements in detail being introduced over older forms of charging machines, and it will be constructed in the already extensive and rapidly extending crane department of Messrs. Babcock & Wilcox, who have started a special branch of their crane department for dealing with steel works special cranes and charging machines. It is the intention of the firm to take up the manufacture of any handling and transporting machines and apparatus for handling the raw material or finished products in steel works.

A PORTABLE BRIDGE AND FAULT LOCALISER.

Although the location of artificial faults in cables can be carried out with considerable precision under laboratory conditions, a mains engineer frequently experiences no little difficulty in obtaining reliable measurements in practice. The liability of introducing errors due to the connecting-up leads, the resistance of temporary joints, &c., in a Murray loop test is well known, so that any means for rendering such allowances unnecessary and for increasing the accuracy of the measurements will be welcomed by mains engineers.

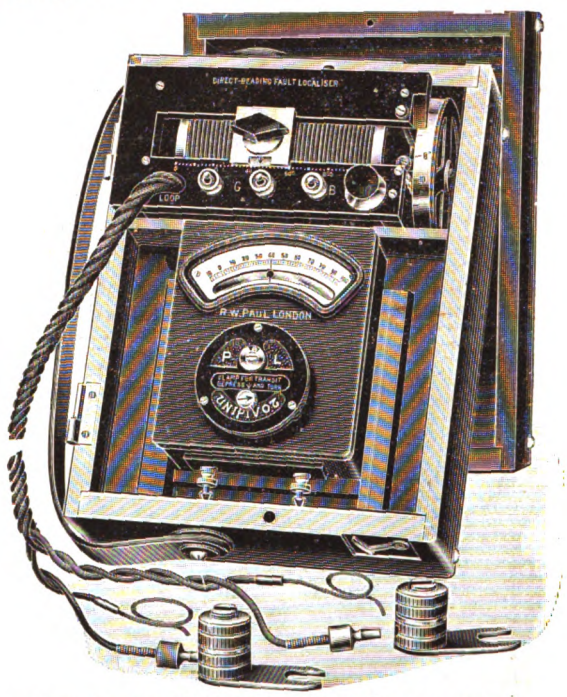

Fig. 1.—New Portable Bridge and Fault Localiser of Mr. R. W. Paul.

Mr. Robt. W. Paul has just placed on the market what is undoubtedly one of the most compact and at the same time reliable portable Wheatstone bridges and fault localisers that we have seen. An idea of its portability and compactness can be obtained from Fig. 1, which shows a general view of the apparatus.

First, as to the use of the instrument for resistance measurements. The bridge wire is about 10 metres long, and is wound on a screw threaded insulated metal drum, mounted in a frame of aluminium and ebonite (see Fig. 2). The bridge wire is connected to the terminals by flexibles, thus eliminating moving contacts, and increasing the accuracy of the measurements.

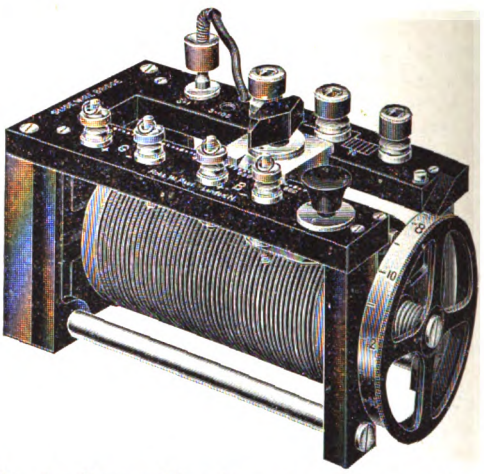

Fig. 2.—Bridge Wire Mounted on Insulated Drum.

Two standard coils are contained in a shallow box at one end of the instrument, and either 1 or 100 ohms may be brought into the circuit by means of a plug. The sliding contact, which acts as a key, is joined in the galvanometer circuit and may be adjusted to any position on the slide wire, firstly by moving the slider which has a device for registering the contact point exactly on the wire, and secondly by rotating the drum. The spindle of the drum is screw threaded to the same pitch as that of the wire and its movement is limited to one turn. The disc is divided into 20 parts; and as there are 50 turns of wire on the drum and the position of the contact may be read to one-tenth of a division, readings may be determined to one ten-thousandth part of the slide-wire length.

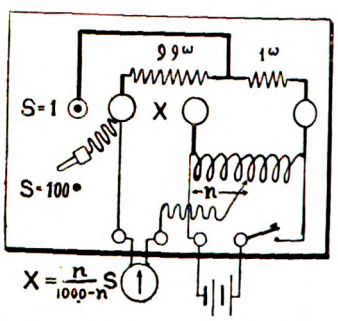

Fig. 3.—Connections when used as Wheatstone Bridge.

All the parts are visible and the wire is easily cleaned. Extra large terminals are provided for connection to the resistances to be

measured. The useful range of this instrument when used as a Wheatstone bridge is from 0·02 to 5·000 ohms, and it may obviously be used as a fine adjustment rheostat or potential divider as well as a bridge.

When arranged for fault localising by the loop test, the terminals joined to the end of the slide wire are replaced by flexible leads permanently fixed to the instrument; their resistance being allowed for in the adjustment of the slide wire. The ends of the leads terminate in plugs (see Fig. 1) which may be inserted in terminals adapted for clamping on to the cable or bolting to a switch pillar. The ease with which the connection can be made and the good contact obtained are certainly features of the apparatus. With these leads are laid up two wires for connection to the galvanometer, each of which wires terminates in a short length of bare flexible, for direct attachment to the cable beyond the localiser terminals. Thus the resistance of the joint is not included in that of the loop.

This localiser is illustrated in Fig. 1 in combination with a low resistance unipivot galvanometer, which is particularly adapted for the loop test.

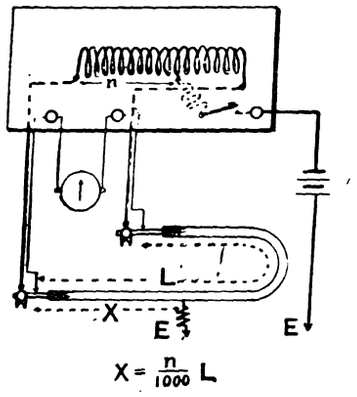

Fig. 4.—Connections when used as Fault Localiser.

The slide wire is capable of carrying 5 amperes without injury, and the current for the test may be taken from the mains by using a lamp in series, or from a small portable accumulator, 1 ampere being usually sufficient.

It will be seen that if the fault were *very close* to one end of the cable it would not be possible to obtain a balance, on account of the resistance of the flexible leads; in such a case a coil of nine times the resistance of the slide-wire may be inserted at the end of the flexible, thus extending the range of the slide-wire.

Fig. 3 shows the connections when the apparatus is used as a Wheatstone bridge, whilst Fig. 4 indicates its application for fault localisation. Even before this apparatus had been placed on the market, its good points were quickly appreciated by those who were privileged to see it in its unfinished form, so that Mr. Paul should be assured of a considerable demand when the capabilities of this fault localiser are more widely known.

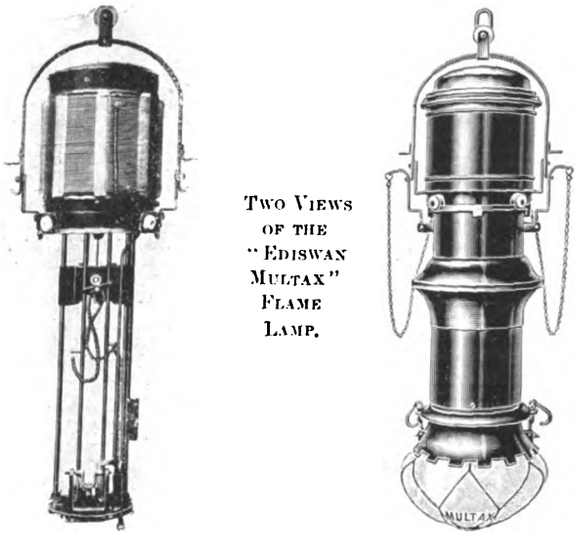
"EDISWAN MULTAX" LAMPS.

Details have reached us of a pattern of arc lamp which the Edison & Swan Co. are putting on the market. It is known as that under the above title, and embodies the "bridge-core" principle for the carbons. By the use of this system of carbons the burning hours of the lamp are doubled without any increase in length of the lamp. This is an advantage where shop-window lighting and low interiors have to be dealt with. The bridge core carbon is also stronger than the ordinary single carbon, consequently breakages are reduced considerably. The working parts of the lamp are carefully enclosed and protected from the fumes given off by the burning carbons. There is no magazine and the lamp is of simple construction. The



Two Views of the "Ediswan Multax" Flame Lamp.

"Ediswan Multax" long burning flame lamp is at present supplied for 20 and 36 burning hours. The 20-hour pattern is recommended because it is only 33 in. in overall length, for all ordinary lighting purposes, and in particular for shops and public buildings. The 36-hour pattern is suitable for street lighting purposes, docks and goods yard illumination, and generally where trimming considerations outweigh the slight disadvantage of somewhat increased overall size.

ALVA A.C. WATTMETERS.

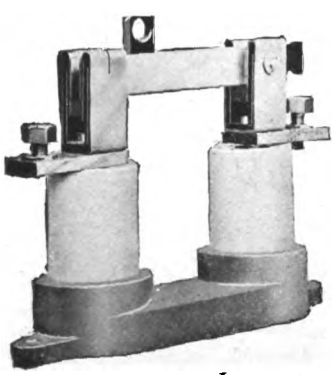
The following general details of Alva wattmeters have been supplied by Messrs. Gillespie & Beales. The "Alva" wattmeter works on the induction principle and possesses the mechanical advantages of the induction type of meter, with the sensibility and accuracy of a wattmeter of the dynamometer type. It can be used for the measurement of single-phase, two-phase or three-phase power consumption, and can be employed as a fixture on switchboards and also as a portable instrument for the testing of dynamos, transformers, motors, &c. The "Alva" wattmeter has a uniformly divided scale and is stated to be accurate at all loads.

The principal difference between the Alva wattmeter and other wattmeters consists in an optical arrangement enabling the indications on a horizontal scale to be read vertically, and thus the moving element can be mounted on a vertical axis, thus rendering the instrument free from any frictional troubles.

The "Alva" wattmeter is made for single-phase circuits, three-phase circuits with balanced loads, three-phase three-wire circuits with unbalanced loads or for two-phase circuits with common return, three-phase four-wire circuits, and for three-phase four-wire circuits (on two-phases and the neutral wire). The torque on the wattmeter disc at full load is from 40 to 50 gramme-millimetres, and the shunt loss of the wattmeter varies from 0·6 watts to about 4 watts according to type. The weight of the disc is about 25 grammes, and the insulation of the meter is tested at 2,000 volts. The accuracy of the wattmeter is said to be independent of the wave form of the alternating current, and is not appreciably affected by considerable variations in the pressure and frequency of the supply.

ISOLATING SWITCHES.

The illustration shows a single-pole isolating switch manufactured by Siemens Brothers Dynamo Works. The standard types are either single or triple-pole, and are slow-break switches mounted on porcelain insulators suitable for pressures up to 6,600 volts. Single-pole switches are arranged for operation by means of an insulated pole and hook. They are made in two designs: For fixing to iron framework, &c., the switch being provided with a cast-iron base, the terminals being arranged for front connection. For cementing directly into brickwork or concrete, this design of switch has no base, and can be supplied either for front or back connection, or with one terminal in front and one behind.

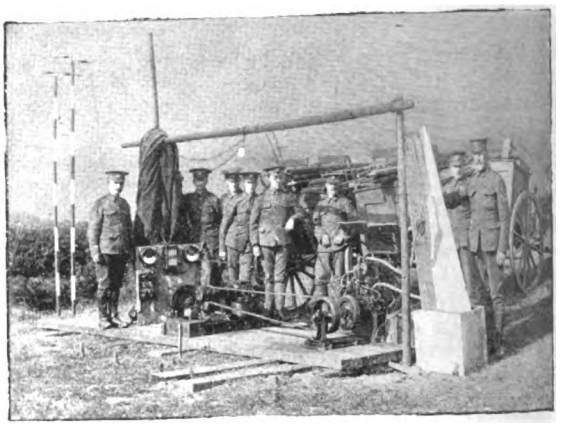


General View of Isolating Switch.

Triple-pole switches consist of six porcelain insulators carrying switch contacts, cemented into a cast-iron base, the connecting blades being also mounted on porcelain insulators, and fixed to a common wayshaft, which can be operated directly by means of a double-armed handle, or indirectly through a system of levers and links. In triple-pole switches the terminals are always arranged for front connection.

OSRAMS ON ACTIVE SERVICE.

The Osram lamp has been responsible for many revolutions in lighting methods, and we have had occasion to deal with these from time to time in our columns. The most recent example to come to our notice is that of camp illumination, Osram lamps being installed at the Bexhill summer camp of the Royal Engineers. The plant comprises a portable 4 H.P. petrol dynamo set, complete with battery. This equipment is used in the daytime to charge the cells for wireless service, and at night provides current for groups of Osram lamps in officers.



Osrams at Bexhill Camp.

mess, sergeants' mess, orderly tent, men's canteen, &c. Overhead lines attached to service poles are used for distribution purposes. The average distance of the lamps from the plant is 300 yds., and they are run on a 50-58-volt circuit. The interior of the waggons carrying the wireless apparatus (as shown in the illustration) are lighted with Osram motor car lamps. This interesting installation affords yet another instructive example of the efficiency and durability of the Osram lamp. The plant was first put into service in August, 1910, and was fitted up by the members of the wireless and airline companies of the London Army Corps, R.E.

A SIMPLE CIRCUIT-BREAKER RELEASE.

In our last issue we gave some preliminary details of a pattern of circuit-breaker manufactured by Morris & Lister, Coventry. We have now been supplied with a drawing showing the details of the release employed in this circuit-breaker, and we think it of sufficient interest to reproduce. Fitted to the breaker is a casting known as "the rocker." In closing the breaker this casting is driven in positively by the handle. The lower end of the casting is fitted with a locking catch which engages as soon as the breaker is home. The top end of the rocker casting carries a turned plunger

catch which engages two flat catches connected to the main arm of the breaker; these two catches are kept in position by tension on the thermal strips. When the breaker is overloaded these strips expand and allow the flat catches to spring outwards, thus releasing the main arm of the breaker, which flies out away from the rocker. The bottom end of the breaker arm is fitted with cam surfaces which release the bottom locking catch. The breaker is immediately ready for closing. For the various attachments such as no-voltage, minimum and reverse current the bottom locking catch is operated on. For instance, in an overload and no-voltage breaker this catch is sprung down so that it will not engage unless there is voltage on the magnet system. Should the voltage fail the catch is released and the breaker opens.

CELL OR SELL?

A Birmingham traveller in the hardware trade was on business in a cathedral city recently. In the office of an ironmonger there he found a derelict dry cell, and as he wanted something of that kind to make a simple experiment, he asked if he might have it. The ironmonger agreed with pleasure. As the traveller had only a few minutes to catch his train he carried away the cell under his arm, without wrapping it up. As he approached the station he became aware of something unusual, and was suddenly pounced upon by an inspector of police, who snatched the worn-out battery from his arm, placed it on the ground, and hustled the unoffending traveller into the station-master's office. A body of police were told off to watch that nobody approached the place where the traveller was confined; indeed, when the whisper went round that an anarchist with a live bomb had been discovered, people scarcely needed telling. In the meantime the poor commercial traveller was subjected to a long string of searching questions. He put his foot in it at the beginning by saying he had no idea the King and Queen were expected to pass through the station. The officials smiled incredulously. Of course, nobody in the city could possibly be ignorant of such a thing. Nor did the traveller mend matters by saying that he knew nothing about the "bomb" except that he believed it to be quite harmless. If it was harmless, what were those curly bits of wire sticking out from it? And when he declared that he had only just had the thing thrust into his hand by a friend, he simply ran himself in. People don't allow friends to thrust bombs into their hands without their knowledge. It was not until the erstwhile owner of the "bomb" had been brought to the scene to corroborate the traveller's statements, and prove the truth of his assertions by taking the battery to pieces, that the traveller was allowed to go free. Even now, he fears, he will be a marked man in the city in question for the remainder of his days.—*From "The Ironmonger."*

EXCELLO

FLAME ARC WITH UNIQUE TWO YEARS' WARRANTY

THE GAS STOVE OF ADOLPHUS BROWN.

Adolphus Brown was very proud,
He moved above the common crowd;
And yet his ways were very loud.

He said his blood was old and blue,
But not a word of this was true;
He was a low-down *parvenu*.

For "common things" he cared no jot,
And therefore he indulged in what
His friends and neighbours had not got.

Now Jones, who was his *ris-a-ris*,
Had told him that, for cooking, he
Believed in electricity

And so had bought a useful stove
That smells and dirt from kitchen drove;
He said it was a treasure-trove.

But Brown turned up his Cockney nose.
He said: "That really only shows
How little everybody knows."

For his conceit was very crass.
He said: "The smart set cook with gas."
He really *was* a stuck-up ass.

He thought such men as Jones were dirt,
Their customs low, their manners pert.
And yet his dignity was hurt.

That Jones should try to do the grand
With stove of the electric brand
Was really *more* than he could stand.

The Gas Co.'s showroom wasn't more
Than twenty minutes from his door.
He bought a stove for five pounds four.

They said it was the *very* best
By London County Council test.
He turned his back upon the rest.

He said: "Please send it very soon;
I'm sure that it will be a boon."
They promised it that afternoon.

He stood beside his garden gate,
He hadn't very long to wait;
He'd bested Jones, at any rate.

They fixed it up that very day:
He said he'd try it, come what may
He'd have his dinner cooked that way.

* * * *

That night when Jones was at his door
He heard a loud and deaf'ning roar,
And something hit him on the jaw.

Although no longer in his youth,
Jones had a strict regard for truth;
He swore it was Brown's wisdom tooth.

And, probably, Jones was quite right.
There fell from out th' Empyrean height
Small bits of Brown throughout the night.

For here they found a lump of fat,
A hand, an ear, his new silk hat;
They even found his old tom cat.

And eke an arm, a nose all hacked;
They found his braces and, in fact,
They found his trousers quite intact.

But of the gas stove ne'er a trace;
No bits were found about the place—
It was projected into space.

And now among the asteroids,
Converted into alkaloids,
It floats, unregistered at Lloyds.

Thus Brown, he proved to you and me
The worth of gas, and paid the fee.
Electric stoves are best, you see.

V. Z.

NEW TURBO SET AT ST. HELENS.

The official opening of the latest addition to the plant in the generating station of the St. Helens Corporation took place on April 5. The new unit consists of one British Westinghouse 1,000 kw. steam turbo-alternator which runs at a speed of 3,000 revs. per min. and supplies energy at a pressure of 6,600 volts.

The turbo-alternator takes steam from the boilers at 160 lb. per square inch, and the steam consumption guaranteed was 15·9 lb. of steam per kilowatt-hour at full load; the actual consumption on test came out at 15·64 lb. per kilowatt-hour, which is 1·63 per cent. better than the guarantee. This result is most satisfactory from the Corporation's point of view. The condenser is of the low-level jet type, manufactured by The Mirrlees Watson Co., with Westinghouse motors driving the various pumps.

The illustration shows the Westinghouse turbine opened for inspection. The steam enters at the left-hand side of the turbine and is expanded through the various nozzles placed in each stage until the exhaust pressure is reached. Each stage consists of a diaphragm fixed in the cylinder and a moving wheel on the shaft. The velocity of the steam after it passes through the diaphragm nozzles is used up on the blades of the moving wheel.

The bearings are supplied with oil under pressure from the oil pump shown in the bedplate of the turbine, which is driven by means of a vertical shaft through bevel gear from the governor shaft, which in turn is driven from the main turbine shaft by means of the worm and gear wheels shown. An emergency governor is fixed on the extreme end of the shaft to prevent the turbine reaching a dangerous speed should anything go wrong with the ordinary governor gear. The blades rivetted on the various wheels are machined out of the solid steel bar. The main shaft is made of high-quality steel, and stepped in diameter from the centre towards each end to take the blade wheels. Water glands are provided on each end of the cylinder to keep air from leaking into the cylinder and steam from passing out. The steam chest, which receives the steam from the main boilers, contains the necessary stop valves and governor valves for operating and controlling the turbine. It will be seen that the turbine is covered with planished steel, and all moving parts are totally enclosed so that no dust or dirt can reach the bearings. The alternator is totally enclosed, and in order to keep the windings cool, air is drawn in at each end of the machine and discharged at the top.

Before the installation of the 1,000 kw. turbo-alternator, the whole of the alternating current generated was supplied by two Westinghouse rotary converter equipments, of 250 and 550 kw. capacity. Now that the turbo set is installed, these rotary converters will form a very flexible and most efficient link between the direct-current and alternating-current systems of supply. Each rotary is reversible, that is, it can supply a.c. or d.c. energy as required.

The whole of the switchgear equipment was also supplied by the British Westinghouse Co.

THE ELECTRICIAN COMMERCIAL AND INDUSTRIAL SUPPLEMENT.

C. & I. Supplement No. 81.] APRIL 21, 1911. [Gratis to Subscribers.

HIGH C.P. METAL LAMPS AT LOWER PRICES.

Shopkeepers, tradesmen and central station engineers will read with satisfaction the announcements of most of the metal lamp makers this week to the effect that the high candle-power lamps are to be again lowered in price. This move will materially assist the electrical industry in its campaign against gas, because the inverted mantle when grouped in suitable lanterns is a most powerful competitor of the metal lamp when used in the same manner. The high candle-power metal lamp should, in the light of its new price, be capable of competing even more successfully with gas than it has already done. In every sphere of trade, commerce and industry, there is a demand —and a big demand—for a unit of light between that of the highest candle-power lamp in general use—the 50 c.p. lamp—and the smallest arc lamp. The most successful high candle-power metal lamp is rated at 600 c.p., and a light unit of this standard is of immense value for the illumination of shops, yards and open spaces. Its selling price is therefore of more than ordinary importance. The action of the lamp makers in reducing prices should be supported by the trade in every possible way.

As far as the central station engineer is concerned his support can no doubt be counted upon for high candle-power metal lamps for street lighting. This is a field in which the gas advocates fear the competition of the metal lamp more than in any direction. The electricity supply authorities have kept up a constant fight with gas for the last few years, and they have succeeded in removing to some extent the popular impression that gas is a cheaper and better illuminant than electricity for streets and public thoroughfares. Already the metal lamp shows a remarkable life when used in this field of illumination, but its initial cost has prevented many undertakings launching out on a big scheme for the conversion of existing gas lanterns or for the fitting out of new posts. The effect of the new prices will be watched with interest, and we hope that both the industry and the manufacturer will benefit by it.

The announcements of the various lamp makers are given below.

MAZDA.

The British Thomson-Houston Co. state they have decided to amend the list prices of high candle-power Mazda lamps, and the following are the new prices :—

Watts.	British candle-power.	Volts.	Dimensions.	List price of clear parallel lamps.
80	53	100/260	6″×3¼″ straight side	4s. 6d.
100	90	100/260	7″×4⅜″ spherical ,,	4s. 9d.
200	180	100/260	9⅛″×6⅝″ ,, ,,	9s.
300	270	100/260	9⅛″×6⅝″ ,, ,,	17s.

600	540	100/260	11¼″×8″ ,, ,,	20s.

Contractors, &c., who have any Madza lamps of the above varieties still in stock, which were purchased since March 15, 1911, and who advise the company of the number and type immediately, will receive a credit for the difference in price.

OSRAM.

The General Electric Co. announce that they have been very successful in the sale of high candle-power lamps, from 100 c.p. to 600 c.p., with a corresponding effect of cheapening the production. They announce that from April 15, 1911, prices will be reduced as follows :—100–260 volt 100 watt, approx. 100 c.p.,

See important announcement, page xv.

4s. 9d. each; 100–260 volt 200 watt approx., 200 c.p., 9s. each; 100–260 volt 400 watt approx., 400 c.p., 17s. each; 100–260 volt 600 watt approx., 600 c.p., 20s. each.

They hope by these reductions to largely increase the sale of the higher candle-power lamps which have an exceedingly long life, as shown by a recent test by the National Physical Laboratory. Further, the Official Records of the Borough of Hammersmith Electricity Department also show that an average life of over 3,600 hours has been attained with Osram lamps.

"ONEWATT."

Messrs. Siemens Brothers Dynamo Works Limited, Tyssen-street, Dalston, London, N.E., have reduced the list prices of their well-known "Onewatt" lamps of 200 c.p. and 400 c.p. The prices of these in all voltages are, as from the 15th inst., 9s. and 17s. each respectively. It is expected that the lower prices will enable contractors to do an even larger trade in these lamps than previously. We may remind our readers that the price of their 100 c.p. lamp remains unchanged at 4s. 6d. A new price list has been printed containing the above alterations, and quantities will be forwarded, over-printed with contractor's name and address, on receipt of application accompanied by trade card.

AEGMA.

The Electrical Co. lamp department are making reductions in the price of their high candle-power lamps as follows: 100 c.p., 100–135 volts, from 5s. 6d. to 4s. 6d.; 100 c.p. 200–260 volts, from 6s. to 4s. 6d.; 200 c.p. 100–260 volts, from 12s. 6d. to 9s.; 400 c.p. 100–260 volts, from 20s. to 17s.; 600 c.p. 100–260 volts, from 22s. 6d. to 20s. The same company also make an important announcement in the reduction of their 25 c.p. and 32 c.p. pear-shaped 200-volt metal lamps. These are both reduced from 4s. to 3s. 9d. These prices are, of course, subject to the usual trade discounts, and we understand that the company is in a position to make prompt delivery. They also state that they can give special terms for street lighting.

BRIMSDOWN.

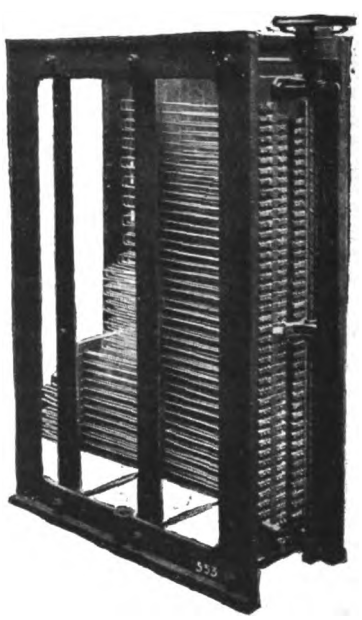
Imperial Lamp Works (Brimsdown), Ltd., announce reductions in the price of their lamps. These affect the lamps from 53 to 540 British c.p., and are as follows: 53 c.p. 4s. 6d., 90 c.p. 4s. 9d., 180 c.p. 9s., 270 c.p. and 360 c.p. 17s. each, and 540 c.p. 20s. These are list prices for clear lamps, and are, of course, subject to the usual trade discounts.

PHILIPS.

Messrs. G. M. Boddy inform us that the prices of their Philips high-candle metal lamps, 100 c.p. to 1,000 c.p., will be reduced to the same level as that of the Osram lamps. Mr. Boddy has been identified with the metal lamp trade for many years past, and has always endeavoured to associate his business with all improvements and developments as they occur.

LARGE CAPACITY RHEOSTATS.

A new line of rheostats for controlling the field circuits of large generators and for other purposes is being made by the Electric Construction Company. They describe it as their straight line type, and the illustration shows a regulator with an operating hand wheel. They are, however, designed also with the view to being placed away from the switchboard and operated by gearing and rods, or by chain.



E.C.C. RHEOSTAT.

The rheostats have a large number of ways, and the resistance conductor consists of a number of strips or wires in parallel, so that the continuity of the circuit does not depend on one strip or wire, and it also enables the ohmic resistance to be readily altered. The hot air rising from the resistance material is not obstructed in any way by the framework, and the ventilation is consequently efficient, enabling a large amount of heat to be dissipated in comparatively small dimensions.

THE SALESMAN'S CREED.

1. To respect my Co. and myself. To be honest and fair with my Co., as I expect my Co. to be honest and fair with me; to think of it with loyalty, speak of it with praise, and act always as a trustworthy custodian of its good name.

2. To make a study of my business or line; to know it in every detail; to mix brains with my efforts and to use system and method in my work. To find time to do everything needful by never letting time find me doing nothing. To make every hour bring me dividends in commissions, increased knowledge or healthful recreation.

3. To believe in my proposition heart and soul; to carry an air of optimism into the presence of possible customers; to dispel ill-temper with cheerfulness, kill doubts with strong

Quick Delivery. *Competitive Prices.*

The Electric & Ordnance Accessories Co., Ltd., Aston, Birmingham.

(Proprietors, VICKERS LIMITED.)

convictions and reduce active friction with an agreeable personality.

4. To remember that success lies within myself, in my own brain, my own ambition, my own courage and determination. To expect difficulties and force my way through them; to turn hard experience into capital for future struggles.

5. To base my expectations of reward on a solid foundation of service rendered; to be willing to pay the price of success in honest effort. To look upon my work as opportunity to be seized with joy and made the most of and not as painful drudgery to be reluctantly endured.

6. To keep my future unmortgaged with debt; to save money as well as earn it; to cut out expensive amusements until I can afford them; to steer clear of dissipation, and to guard my health of body and peace of mind as my most precious stock-in-trade.

7. Finally, to take a good grip on the joy of life; to play the game, and to endeavour to grow as a salesman and as a man with the passage of every day of time. This is my creed.

The foregoing has been sent in to us by the St. Helens Cable Co. who are making a distribution of them to applicants (strictly in rotation). Mr. J. C. H. Brooking, the manager of the company in question, is responsible for this *credo*.

We have numbered the items for purposes of comment. It will be noticed that there are seven. The author evidently believes in the biblical number.

Nos. 1 and 2. Rather difficult with a man who sells turbines, condensers, metal lamps, varnish, rubbers, telephones and electric winders, all in the space of about 18 months. He makes his own creed as he goes along.

No. 3. Not recommended for salesmen of steam turbines.

No. 4. This should be a boon to salesmen of magazine arc lamps.

No. 5. Borough electrical engineers in small towns with salaries from £150 a year downwards should frame this item in solid oak, or, better still, have it perpetually reeled off on a phonograph.

No. 6. Impossible for electrical contractors and advertisement solicitors. Simply can't be done.

No. 7. Electrical men generally might omit the repetition of this the next time they go to church.

We suggest as a substitute: Finally, to get a good grip of the other man's prices, to cut like blazes, and to endeavour to get the job (*for the works' sake*) every time and all the time.

COLOUR CAPS.

Electrical contractors and central station engineers who have in hand illumination schemes for the Coronation will be interested in a device for illuminating the tips of lamps which is being put forward by an American firm, Messrs. Betts & Betts, of New York. This company has sent us a number of bulletins in which this interesting device is described. It is a celluloid cap which is clipped on to the lamp bulb by wire fasteners which encircle a flange at the base of the cap. A stock series of colours is listed, and we understand that a supply can be given at short notice. The makers claim that the cap has an advantage over a dipped lamp, in that it cuts off a minimum of light, and, in fact, enables a lower candle-power to be used with the same effect as a higher candle-power with a dipped lamp. The company have supplied a large quantity of these caps to the big sign firms in America, and the literature supplied contains illustrations of a number of these signs.

OSRAMS FOR STREET LIGHTING.

In a recent issue we reviewed a publication which the General Electric Co. had issued relating to the application of the Osram lamp for street lighting. This booklet contained a page from the log book kept by Hammersmith Borough Council of the street lighting lamps, all of which are Osrams. We have now received an extract from this log relating to the life of 75 lamps, and the figures are of sufficient interest to publish in full.

Total number of lamps ..... 75.
Total burning hours ..... 270,988½.
Average life per lamp ..... 3,613 hours.

The following are a few instances of existing large street lighting installations :—

The Corporation of Torquay have replaced every arc lamp previously on circuit by 1,000 c.p. Osrams, 80 of the latter now being in use. At Acton 64 400 c.p. Osrams have replaced a similar number of 10-ampere open-type arc lamps. In Hammersmith a considerable number of 400 c.p. Osrams have replaced arc lamps in one of the most important thoroughfares. According to figures now to hand, we understand this change has been the means of effecting a saving of £2. 16s. per lamp per annum. Yarmouth Corporation have installed over 300 400 c.p. Osrams which replace both arc and gas lamps. West Hartlepool have a number of 200 c.p. Osrams now in use, these having displaced 10-ampere open-type arc lamps. Wimbledon have already installed 49 300 c.p. Osrams, most of which have replaced 550-watt small enclosed arcs, whilst over 1,100 50 c.p. Osrams are being used in this district for side street lighting. Cardiff have already replaced over 60 arcs with 400 and 600 c.p. Osrams. Bury St. Edmunds have 200 Osrams in use for street lighting and a further 200 posts are being fitted. The lamps are of the 63-watt 200-volt type and their average life is found to be about 2,500 hours. A life of 2,000 hours is also reported from King's Lynn, where there are 600 Osram lamps in service for street lighting. We may also mention that a contract has been placed for the supply of 4,000 Osrams for the entire equipment of the incandescent lamp street lighting scheme for Johannesburg. On the Underground Electric Railways, London, some thousands of high candle-power Osrams have been installed, entirely replacing the arc lamps which previously provided illumination for their various stations.

IFS AND QUERIES.

If the writer of the "Electricity Memoranda" in the "Journal of Gas Lighting" were not a Scotchman.

With the new electric train service will the I.E.E. Conversazione be held at the Crystal Palace this year?

How much longer will metal lamp makers resist the temptation to reduce prices all round?

If the miners succeeded in prohibiting the use of electricity in mines what would all the gas works do?

Will the additional 54,000 c.p. in the street lighting at Watford adversely affect the dividends of the local breweries?

Carnarvon Castle is to be lighted electrically for the investiture of the Prince of Wales; will the castle electrician arrange for the necessary leek?

If Mr. Killingworth Hedges were made Comptroller of the P.O. Telephone System.

After the events in Holborn, will the Street Lighting Committee of the Corporation of London now ask for a scheme of public lighting to be submitted by the gas and electricity supply companies jointly?

IF WEATHER-PROOF CABLE—WHY CONDUIT ?

One of the leading cable companies has recently introduced a Rust and **Weather-proof Cable,** specially recommended for use in Screwed Steel Tube ; a **Conduit Company** advises that **Weather-proof Cables** be used in their conduits. Why ? Because it is impossible to have steel or iron tubes without condensation.—It means that **no** cable ordinarily used for indoor work should be drawn into steel tubes. The Weather-proof Cables are certainly more suited to the conditions, but they don't eliminate the condensation—the trouble is still there.

And yet **"Conduit wiring without condensation" is possible,** and easy of attainment—but only with the **Kalkos System** (taped only wires are all that are required). That is why a constantly increasing number of consulting engineers are specifying, and contractors adopting it as their standard practice. Write now for full particulars of the Kalkos system which is guaranteed free from condensation by The Sun Electrical Co., Ltd., 118-120, Charing Cross Road, London, W.C.

"STANNOS" AT RHYL.

RESULTS OF 12 WEEKS' CAMPAIGN.

Towards the end of last year, the Rhyl Urban District Council wished to increase the load on their mains, and Mr. E. H. Wright, the electrical engineer, approached Messrs. Siemens Brothers & Co., as it was considered that Rhyl would

EXTERIOR OF "STANNOS" SHOWROOM AT RHYL.

offer an excellent field for the O.S. wiring system. Eventually the Council fitted out a showroom, which was wired throughout with "Stannos" and opened early in January. The necessary advertising was undertaken by means of signs, lighting, showboards, literature, newspapers, &c. Simultaneously an energetic canvass of the town was made by the two local contractors, Messrs. D. T. Jones & Co. and Mr. Barker, who have obtained between them, a large number of orders for new installations with "Stannos" (including "Tantalum" lamps and "Zed" fuses). The additional load secured to the undertaking by the 12 weeks' campaign is represented by the equivalent of over 1,100 30-watt lamps.

The importance of these figures must be considered, however, in relation to the size of the undertaking. Taking as a basis the latest published data (THE ELECTRICIAN Tables of Electric Lighting, &c.), the lamps connected represent an increase of about 11 per cent. We understand that Messrs. Siemens Brothers & Co., Ltd., are prepared to discuss "Stannos" showroom schemes with station engineers who are desirous of providing the necessary facilities much on the same lines as at Rhyl.

Since Messrs. Siemens Brothers & Co. first introduced the wiring about two years ago, one of their claims has always been that "Stannos" wires provided a means for increasing the number of consumers. With that object indirectly in view, they instituted a publicity campaign, which was applied at both ends of the retail scale, viz., the contractor and the consumer, and the results continue to afford the greatest satisfaction. This is particularly the case in localities where prejudice or conservatism is not allowed unduly to influence progress, and where the station engineer is able, or enterprising enough, to assist. The foregoing shows how it can be done.

NEW TRADE LITERATURE.

A budget of trade publications has reached us from various sources during the past week.

The British Thomson-Houston Co. has sent particulars of their arc lamp winches, high torque alternating-current watt-hour meters, pressure governors, radiator lamps, automatic starting compensator, automatic starting rheostats for direct-current non-reversing motors above 15 H.P., and oil-immersed switches for induction motors. We shall give details of one or two of these specialities in our next issue.

The General Electric Co. have issued several catalogues which relate to their engineering supplies and arc lamps and accessories. The former describes a variety of small type Witton motors, and shows the application of these to machine tools, small pumps, sewing machines, coffee mills, vacuum cleaners, &c. There is also a section dealing with accumulators, dynamo supplies and traction overhead equipment accessories. The arc lamp list is replete with information on the subject of Angold and Butt arc lamps, and practically every description of lamp manufactured by the company. There is a section on accessories and flame and ordinary carbons. Accompanying these catalogues is a loose leaflet describing the Jackson semi-automatic door switch and Hileach patent shade carrier. Particulars of these will be given next week.

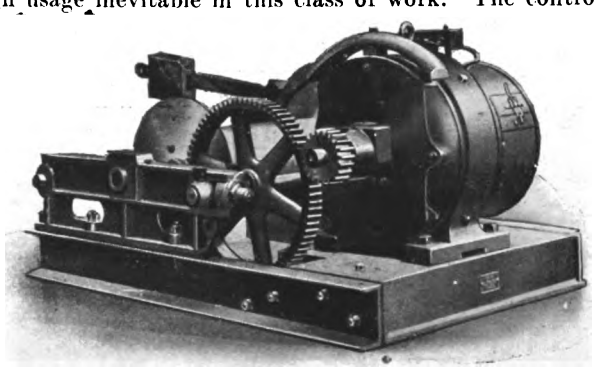
"UNION" FRICTION HOISTS.

These hoists have been designed to meet a general demand for a cheap and reliable electrically-driven winch, especially in connection with building construction. They are constructed with a view to compactness and portability, but at the same time are proportioned to withstand the hard wear and rough usage inevitable in this class of work. The control of



UNION ELECTRIC FRICTION HOIST.

the hoist is effected by a single lever, operated by a rope from any convenient position. The hoists are listed for use on direct-current circuits or three-phase circuits of 50 cycles. In the case of direct-current hoists, the motor is a shunt wound enclosed ventilated machine of suitable speed and output, and the switchgear an ironclad combined switch and fuses, together with a semi-enclosed motor-starter fitted with a "no-volt" release. For three-phase circuits the motor is a squirrel cage enclosed ventilated machine, controlled by an iron-clad combined switch and fuses, and an enclosed star-mesh controller.

The hoists consist of a protected electric motor, driving by means of spur gearing, an intermediate shaft, which carries a small steel friction wheel. The rope drum and a large cast-iron friction wheel are mounted on a second shaft, which is bushed at one end in a swivel bearing, and at the friction wheel end in an eccentric block, capable of being moved through a small angle by means of the operating lever. This lever is weighted so as to bring the large friction wheel into contact with a wooden brake block in its normal position. On lifting the control lever the large friction wheel is first brought clear of the brake block, in which position the rope drum is left free to revolve under the weight of the load, and so lower it; while, if the lever is lifted still further, the large and small friction wheels are brought into contact, and the load is consequently lifted.

The usual method of employing these hoists for building purposes is to instal the machine on the ground level, the wire cable being brought up to the top of the scaffolding, where it is passed over a suitable head wheel. The controlling rope is also led up and over a small pulley, and terminates in a loop into which the operator places one foot. This enables him to keep the hoist under perfect control, and ensures that the friction wheels will be engaged quickly and without slipping, thus reducing wear to a minimum. The Union Electric Co. will furnish additional particulars on request.

THE ELECTRICIAN COMMERCIAL AND INDUSTRIAL SUPPLEMENT.

C. & I. Supplement No. 82.] APRIL 28, 1911. [Gratis to Subscribers.

"SIMPLEX" FOR THE POCKET.

A 400-page quarto catalogue compressed into a pocket edition of 130 pages; it sounds almost impossible, but Messrs. Simplex Conduits have managed it, and we hope that the trade will appreciate their effort by getting and keeping the list, the while, of course, they act upon its many admonitions to purchase. There are no less than 18 sections, and they cover the entire range of wiring and electricity using devices. A most valuable section is that of some 6 pages devoted to a numerical index of the items in the catalogue. The list is 4 in. by 8 in., and can easily be slipped into the catalogue. The illustrations are on a small scale of course, but perfectly clear and distinct. The adjoining specimen is taken from the electric fixtures section, and shows a line of illuminated mirrors for shaving and hairdressing purposes. The mirror is adjustable and can be placed either on the table or hung on the wall.

SEMI-AUTO DOOR SWITCH.

The ordinary automatic door switch is usually under the disadvantage of being switched on every time the door is fastened, whether it is required or not. With the "Jackson" type the light is on only when actually required after entering room, the closing of door and subsequent pulling of cord places the switch in the "on" position. The action of opening the door to leave automatically throws the switch to the "off" position. A considerable saving in current consumption is effected, as during the hours of daylight the switch need not be used. The illustration shows the method of fixing the switch. The device is made by the General Electric Co., who supply the switch for right or left hand doors. There is also included a bolt with 3 ft. cord and acorn-shaped knob.

B.T.H. AUTO-STARTING COMPENSATOR.

Automatic starting compensators are recommended for the remote control or automatic operation of two and three-phase induction motors with squirrel-cage rotors of 5 H.P. and upwards. These compensators are particularly adapted for use with motors in connection with pumping systems.

The compensator method of starting the squirrel-cage type of induction motor presents advantages over the system in which resistance is used in series with the stator for reducing the current taken from the line. In starting a motor with this latter type of device, the line current is at all times the same as the motor current, and since the starting current will probably be several times greater than the normal load current, serious disturbance may be caused in the line voltage.

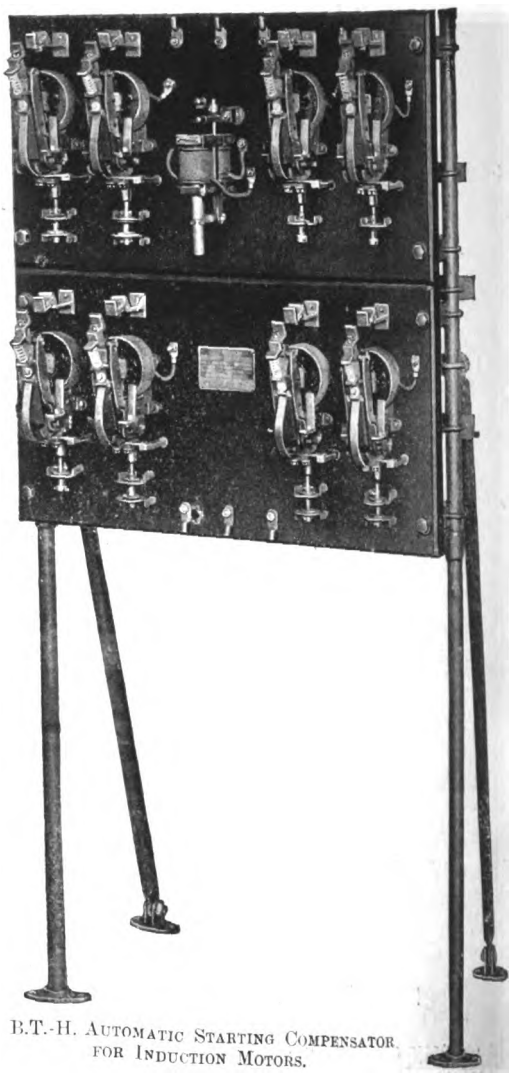
With an automatic compensator the line current during the period of starting is about the same as the motor current at full load, owing to the transformer action of the compensator. In addition, the compensator is provided with tappings which can be adjusted to suit the starting conditions.

The automatic compensator is operated by an improved type of a.c. solenoid, which ensures positive action. In addition, it is possible to instal the apparatus where continuous current is not available, and without the use of batteries or other auxiliary appliances. The only solenoids in circuit after the motor has attained full speed are those on three contactors, and they use a very small amount of energy. Automatic compensators protect the motor if the voltage fails; external enclosed fuses also are provided, which are in circuit only when the motor is across the running side of the automatic compensator.

The B.T.-H. compensator, shown herewith, consists of a current limit relay, contactors, compensator coils and fuses mounted on a panel supported by pipe frame work. The contactor will carry its rated current continuously with a large factor of safety. It opens and closes with a quick positive action, thus preventing fusing at the contacts. It will open the circuit on heavy overloads, arcing being dispersed by means of a powerful magnetic blow-out. Special attention has been given to these contactors in order to eliminate the noise and vibration often experienced with alternating current magnets.

Fuses for overload protection are supplied and mounted on the panel. As they are not connected in circuit during the period of starting, fuses of the running capacity of the motor can be used. All the parts have been designed and constructed to meet the requirements of the severest service, and to enable replacements to be effected with the greatest ease and in the shortest time.

The motor can be controlled either by opening and closing the circuit of the solenoids by means of a small lever switch, or by leaving this circuit closed, and using instead a double or triple pole switch (preferably of the oil type) for opening and closing the line circuit. When the operation of the motor depends upon the rise or fall of a liquid in a tank, a single pole float switch is used to open and close the exciting circuit of the controlling solenoids.



B.T.-H. AUTOMATIC STARTING COMPENSATOR FOR INDUCTION MOTORS.

Starting compensators are supplied in voltages 110 to 550, but they can be supplied for circuits of 2,200 volts. The general construction of high voltage is similar to that of low voltage compensators, excepting that in the former the contractors and the whole of the lower part of the panel are totally enclosed in a tank of oil, thus ensuring perfect insulation and disruption of the arcs at the contacts. Tube expulsion fuses are supplied and a transformer is furnished to reduce the line voltage to the voltage at which the solenoids are operated.

(Proprietors, VICKERS LIMITED.)

NEW ACCESSORIES.

An insulated switch lampholder specially designed by Messrs. Siemens Brothers Dynamo Works (Ltd.) to meet the requirements of the Home Office, is shown herewith. It complies in every respect with the regulations governing the use of pendant switch lampholders in factories and workshops (*see* Regulation No. 13, Factory and Workshop Acts). The lampholder consist of a fireproof insulating case enclosing the porcelain interior of a switch lampholder.

The following advantages are claimed by the makers: When the lamp is in place neither the lamp cap nor any metal part of the holder can be touched. The metal shade is insulated from the lampholder, and therefore cannot become charged. The metal pin which passes through the centre of the switch handle is insulated from the current-carrying parts, so that, in the event of this handle becoming broken, it is impossible for anyone to receive a shock. The insulating covers form an integral part of the lampholder, making it impossible for the lampholder to be used if any portion of the protecting devices is omitted. The lampholder is constructed to take the standard size of shade with 1⅛ in. hole.

The essential function of a gallery is to securely hold the glass shade or reflector or pendant or electric light fitting, and it should be of neat appearance and well finished. The new "screwless" gallery has advantages owing to its simplicity of fixing, and it should appeal to contractors. It is specially deep in order to bring metal filament lamps into correct position in the glass shades, and, in the case of stiletto and household holophane reflectors, brings the lamps into the true focus of the glassware. The "screwless" gallery is a brass spinning drilled and slotted to obtain the necessary amount of spring, having a curved lip which just grips the glassware. A ring slides on the outside and this is pulled up whilst the gallery is sprung on to the lip of the glassware; the ring can then be pressed down to ensure security. To release, the ring is simply pushed up and the glass pulled out. Former types of gallery in which screws are employed are often a cause of breakage because the screws hold the reflector too tightly, and the reflectors crack through expansion. It will also be noticed that the "screwless" gallery is well ventilated, and thus the cap end of the lamp is kept cool. Owing to the shape of the gallery itself, the ring cannot be removed except by force, and the gallery may be considered as far as all practical purposes are concerned as a single piece, rendering the loss of parts, so common in ordinary screw galleries, absolutely impossible. Large stocks of these are being held at all the branches of Messrs. Siemens Bros. Dynamo Works (Ltd.), from whom they can be obtained at the price of 6s. per dozen, list.

SIMPLEX CORONATION ILLUMINATIONS.

There are many and varied devices in connection with illuminated decorations which will, in some shape or other, be used at the Coronation.

The illumination strip already sold by various makers might probably encompass the world, even a few times.

The general public have just begun to think about how much they will spend on decorations, and from the last week in May to the second in June there will be a big rush of orders, which, we understand, Messrs. Simplex Conduits (Ltd.) will be ready to meet with immediate delivery.

They are putting on the market temporary lighting material in the form of strip lighting following on the usual design which is suitable for festoon purposes and outlining buildings (Fig. 1). The holder consists of a galvanised steel case enclosing the usual form of china interior. This is mounted on an insulating base which forms a batten that may be screwed to the face of the building, so that there is no strain on the wire. The wire is twin 7/22's of a high grade, and the insulating base is treated with black enamel, thus protecting it against the attacks of moisture. The wiring is rendered watertight by bitumen filling.

In addition to the wired illuminating strip, a cheap and effective holder is being introduced; this is illustrated in Fig.2.

The method of wiring is extremely simple; the illustration shows the holder apart. The cap is first fixed by an ordinary wood screw, thus securing the insulating piece of fibre shown. The twin wire is then laid in the two grooves provided in the gap, and the lampholder assembled in the usual way. Instead of having to insert a bight of the wire into the lampholder terminals, as is usual, these terminals are threaded, and a brass screw with a spiked end provided. When the lampholder is in position the screw is turned home so that the sharp end pierces the insulating covering of the wire and makes contact with one of the conductors. The holder is accurately shaped, the wire fills the hole in the case exactly, and a practically watertight joint is made without the use of any filling. It is undoubtedly one of the simplest, and at the same time most effective, types of quick wiring holder on the market we have yet seen.

Suitable grouped designs have also been got out in connection with illuminating devices, and one pattern is illustrated in Fig. 3. It is built of wire and sheet metal, and obviates any special constructional work in fixing to buildings. The letters are made in one size, 36 in. high, and require a total of 50 lamps to illuminate the complete device consisting of G.R. and a crown The reflectors behind the lamps give a pretty effect at night. It is recommended that the lamps be pip obscured, and the reflectors can be painted any colour, in which case it is advisable to lacquer the lamps the same colour.

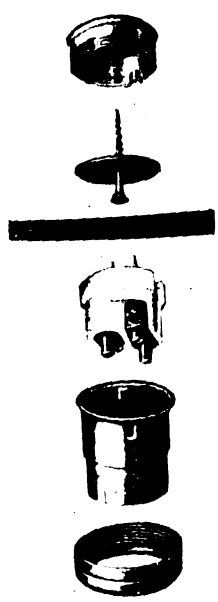

Fig 1.—Simplex Strip Lamp. Fig 2.—Simplex Quick Wire Holder

Simplex Conduits are also introducing illuminated wood letters in various sizes with crowns to match.

For purely decorative purposes, or for use in connection with shade carrier temporary lighting holder, coloured gelatine lanterns are offered. These are in a collapsible form, readily stored or sent through the post, and may be obtained in various colourings as required. With a low candle-power elec-

tric lamp inside they are very effective. Two sizes are supplied: No. 1 pattern, 4½ in. by 4½ in., and No. 2, 6 in. by 5½ in.

The attention of contractors and station engineers is also directed to Simplex electric signs. These are now well known, and require no further description. They are being fitted with a coloured device representing the King or Queen's head, combining both a day and night effect. These signs are 12 in. in diameter, and the price includes lamp, flexible cord, plug and combination wall plug and lampholder adaptor. The sign may, of course, be subsequently used to advertise tradesmen's own goods at the cost of a few pence for a stencil after use in connection with Coronation illuminations.

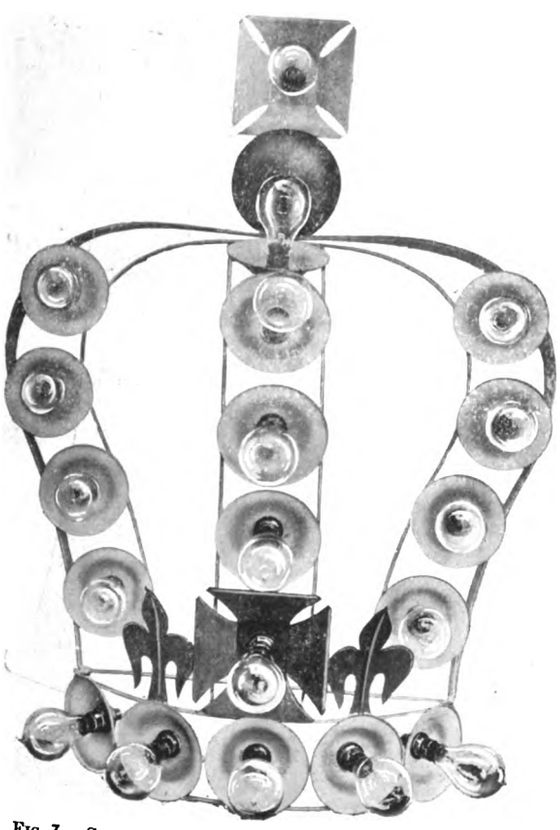

FIG. 3.—SIMPLEX CROWN WITH LAMPS AND REFLECTORS.

The Simplex flagstaff should be very popular among the electrical fraternity. It may be erected or dismantled in a few minutes, and it is not necessary to dig a hole in the ground to secure a firm fixing. It is made up of Simplex steel tubing, and includes lower and top mast, flanged cross trees, rope rigging, truck, flag halliards and Union Jack or Red Ensign. We must congratulate the company on this smart idea.

A NEW AUTOMATIC WATER EJECTOR.

The Ejecta Valve has been designed to overcome the water difficulties encountered in connection with the use of compressed air. It is designed to automatically eject the accumulation of water from the pipe-lines, thereby insuring the delivery of dry air to the machinery which is being operated thereby. The valve is actuated when sufficient water is accumulated in the valve chamber, thereby lifting a float and opening the outlet valve against the pressure of the unbalanced piston. As soon as the water is ejected by the pressure on the line, the float falls and the valve is closed by means of the unbalanced piston, thereby making it impossible for any air to escape after the accumulated water has been discharged.

The advantages claimed for the valve are its automatic action, exceedingly small size (being only 6½ in. × 4½ in. over all) and its light weight; it can be inserted in the pipe line without any special fixing, and is, in consequence, inexpensive to fit. It is constructed of gun-metal throughout, with a copper float, and in such a manner that it can be opened for examination as necessity arises; and its wearing parts are reduced to a minimum. It will work under any pressure without any adjustment whatever. It is already in use on several railways, and we understand is giving every satisfaction. It is made by the Ejecta Valve Co., 110, Cannon-street, E.C.

B.T.H. OIL IMMERSED SWITCHES.

A squirrel-cage induction motor when thrown directly on the line will take a starting current of from 4½ to 7 times full load current, and will develop a starting torque of from full load to 1½ times full load. From these figures it will be seen that on large motors this starting current is excessive, while the torque for most requirements is unnecessarily high.

To reduce this starting current it has been the practice to use an auto-transformer or compensator, or else to bring out six terminals on the motor, so that in starting up the three phases may be connected first in star and then in mesh. The star-mesh switch gives the same results as a relatively expensive compensator with a tap at about 58 per cent. voltage, and the starting current and starting torque are reduced to one-third the value corresponding to full voltage.

Motors with the star-mesh switch will therefore start with about 1¾ times full load current, and give approximately one-half load torque. Hitherto the equipment necessary for controlling a motor started on this principle has consisted of a main switch with a low voltage release, three fuses, a special starting switch, and in some case an ammeter.

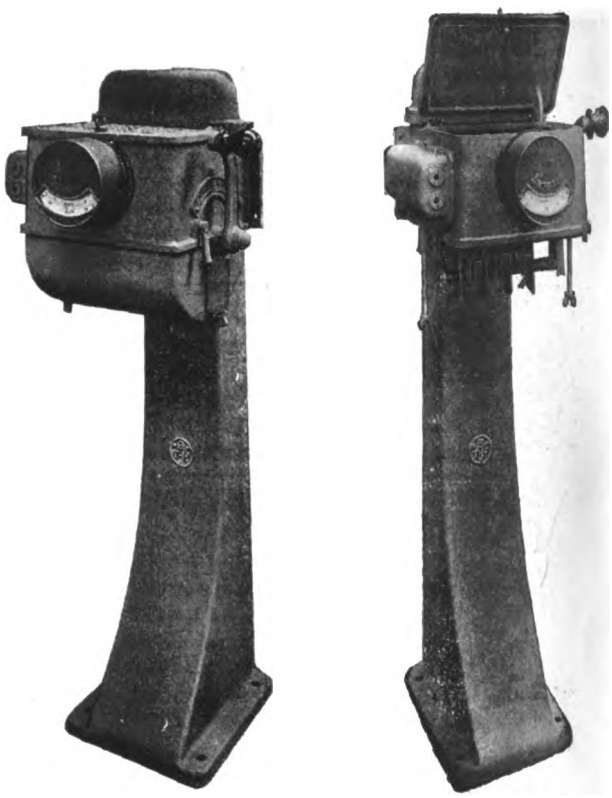
The "O T" switch, made by the B.T.-H., combines in one ironclad unit these devices, and thus provides a maximum of simplicity in the controlling gear as well as in the motor.

All the parts are enclosed in a cast-iron casing, the upper portion of which is fitted with a hinged lid and contains the terminals and fuses; the lower portion is fitted with a semi-circular oil tank which contains the contacts of the oil switch. The joints between the hinged lid and the frame, and between the oil tank and the frame, are so constructed that the whole switch is dust-tight and weather-proof.

All live parts of the switches are of wrought copper. The main blades of the switch are of the lever type, entering U-shaped contacts. Copper beading contacts are provided, so that the circuit is not made or broken on the main contact itself.

The terminals and contacts are mounted on an oiled slate base with a liberal leakage surface between contacts. A removable insulating barrier is provided on the top of the slate base to cover all the terminals, so that there is no possibility of touching live metal when replacing fuses. Punched metal terminals with ⅜ in. diameter tinned holes are provided inside the switch casing, into which the incoming cables may be soldered. If "O T" switches are to be installed in positions where the use of solder is objectionable, they can be furnished with terminals fitted with set screws for clamping the cable. The use of soldered terminals is strongly recommended wherever possible. If clamp terminals are used, they should be carefully tightened up, taped and varnished, both to prevent corrosion at the joint and to provide against the set screws working loose.

The switches are operated by a handle on the right-hand side. This handle is arranged so that when it is in the central position the switch is open; when the handle is pulled towards the operator it is in the starting position, and when it is pushed away from the operator it is in the running position. A quick make-and-break are obtained, and an interlock is provided to prevent the switch being thrown into the running position unless it is first thrown into the starting position. This interlock also ensures the switch being thrown quickly from the starting to the running position.



TWO VIEWS OF THE B.T.-H. OIL IMMERSED SWITCHES.

The switch can be operated with one hand, as the low voltage device is so arranged that it automatically sets itself when current is thrown on to the coil. The fuses can be replaced by opening the hinged lid at the top of the switch. This lid is interlocked with the switch mechanism, so that it cannot be opened unless the switch is in the off position, and when the lid is open, the switch mechanism is interlocked with it, so that the switch cannot be moved from the off position until the lid has been closed. It is, therefore, impossible for an operator to get a shock whilst replacing fuses.

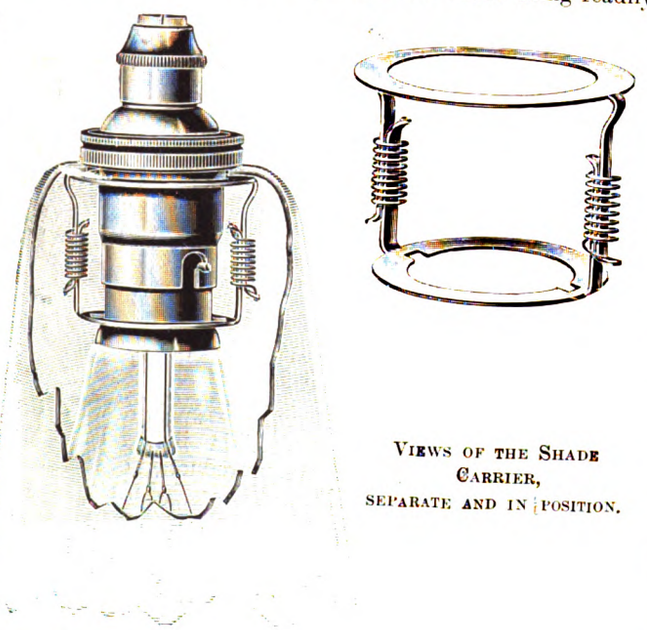
THE ELECTRICIAN COMMERCIAL AND INDUSTRIAL SUPPLEMENT.

C. & I. Supplement No. 83.] MAY 5, 1911. [Gratis to Subscribers.

THE "HILEACH" SHADE CARRIER.

The "Hileach" Patent Shade Carrier is a spring device enabling the shade to be fixed on to lampholder in a remarkably short space of time. It also permits the shade being readily removed for cleaning without unscrewing a shade ring, a necessary operation before the introduction of this ingenious time-saving device. The illustrations show the device itself, and the method of fixing for the shade. There can be nothing more trying than the removal or attachment of an ordinary shade ring, this being the cause of frequent breakages and much spoiling of good temper. The G.E. Co. will supply details of prices.



VIEWS OF THE SHADE CARRIER, SEPARATE AND IN POSITION.

"ZED" PROGRESS.

The success of the "Zed" fuses as a reliable protection for electric lighting and power installation is emphasized by a communication to the "Electrical Contractor" from Mr. Sydney W. Baines, which reads as follows:—"With reference to the enclosed fuse regulation, will you please make known to the contractors of the Association the following:—That, provided the fuses are protected in a similar manner to the 'Zed' fuses—with porcelain—and that no metal parts charged with current are exposed, we do not intend requiring any further protection; that is to say, the teak box lined with asbestos will not be asked for."

An extract from Rules reads as follows:—"On and after January 1, 1911, all main fuses should be of the enclosed cartridge type, built up of porcelain."

The essential feature of the "Zed" fuse is the enclosure of all live contacts, and also the complete enclosure in a sealed chamber of the fusible portion. This construction is a safeguard from fire. Some tests recently carried out by the Burma Electric Tramways & Lighting Co., Ltd., of Mandalay, also illustrate the reliability of "Zed" fuses under severe conditions, and their suitability for tramway work. A "Zed" fuse placed in a feeder circuit behaved perfectly whether under a normal overload in actual practice, under a gradually increasing load or under a dead short. These fuses are made by Siemens Bros. Dynamo Works.

PRESCOT WELDERS.

The progress made in electric welding has been recorded in these columns from time to time, and we are pleased to note that the Prescot welder is being rapidly developed along practical commercial lines. A pamphlet has just been issued in which new and interesting applications of the Prescot welder are illustrated and described. This pamphlet deals with spot and seam welding. A spot welding machine is suitable for welding together two or more plates of iron or steel ranging in thickness from 0·015 in. or 28 S.W.G. to 0·5 in. or 7 S.W.G. The electrodes in the welder are water-cooled, and in the general construction of the machine the operator is safe-guarded from shock.

The general appearance of a spot welding machine at work is illustrated in Fig. 1. This also shows the great variety of

FIG. 1.—PRESCOT SPOT WELDER.

metal utensils and other articles to the assembly of which the welder can be applied. Fig. 2 is a striking illustration of the strength of spot welding. This is a reproduction of some test pieces from Lloyds' proving house. The welded plates shown have been forced apart when cold with a hammer and chisel.

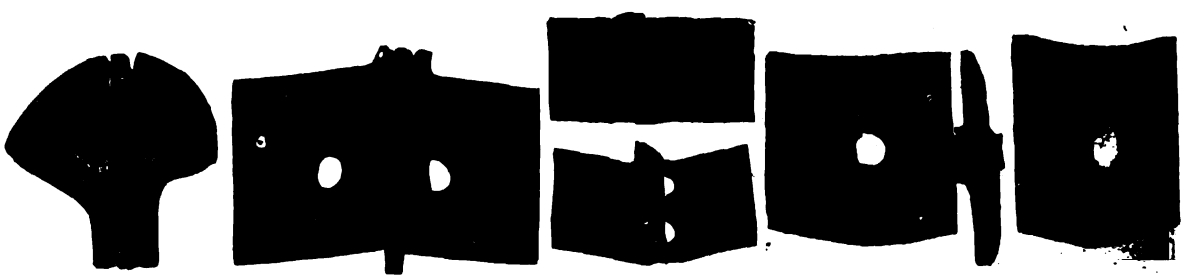

FIG. 2.—EXAMPLES OF PRESCOT SPOT WELDS AFTER OPENING WHEN COLD.

The mechanical effect of the weld is equivalent to that of rivetting. The diameter of the spots will vary from $\frac{1}{8}$ in. to $\frac{1}{2}$ in., according to the gauge of the plate. One phase A.C. current is employed, and if a D.C. or polyphase supply are available they must be converted to one-phase. Standard Prescot welders are wound for 200 volts 50 periods. We understand that the energy consumption is very low; 1,000 $\frac{1}{8}$ in. diameter welds can be made on 28 S.W.G. plate with an energy consumption of $\frac{3}{4}$ unit. In 7 S.W.G. plate 1,000 $\frac{1}{2}$ in. welds can be made with an energy consumption of 70 units. It will be seen that the separation was only effected after large holes had been torn in one or other of the plates.

For seam welding the Prescot welder is also admirably suit-

able. In this process thin plates of wrought iron or mild steel are welded along the edge by a continuous lap weld. Scale and rust are removed because these offer a high resistance to the passage of current. Sand blasting or rotary cleaners must be used to clean the edges of the plate. Plates of 28 S.W.G. and up to 10 S.W.G. gauge can be successfully seam welded at the rate of 1 ft. in 1½ minutes with an energy consumption of 0·2 to 0·3 unit per foot. Fig. 3 shows one pattern of Prescot seam welder which has been adapted from spot welding by replacing the electrode with a pair of rollers. The machine is intended for short welds such as small jugs or for fixing the spouts to jugs. The rollers are closed by a foot pedal, and the top roller can be rotated by hand through a ratchet gear, while the bottom roller is carried round by friction. Cylinders and cones can be successfully welded, and there are also machines for lap welding mild steel tapes such as are used for cable armour and also for the welding of the ends of band saws. The Prescot welder is made by the British Insulated & Helsby Cables, and the booklet referred to above can be obtained from them on application.

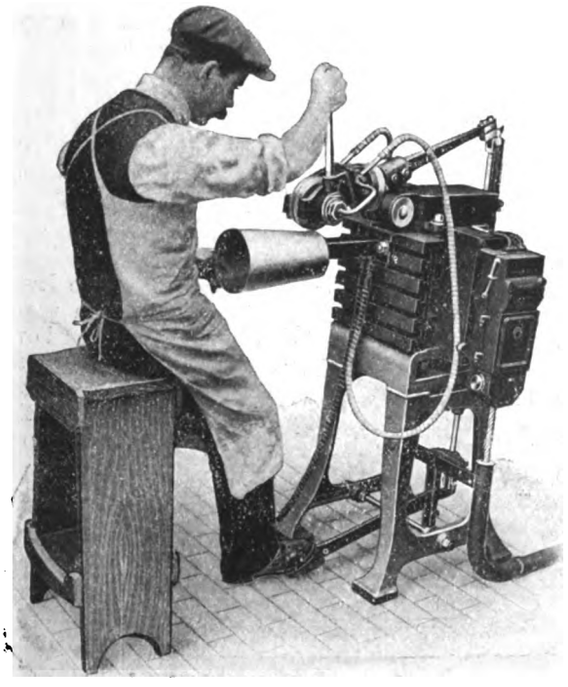

FIG. 3.—PRESCOT SEAM WELDER.

ADAMS DIMMERS.

The dimmer is now universally employed for theatre stage lighting, and it is interesting to note how the metallic dimmer has gradually taken the place of the liquid dimmer. This fact is emphasised in a pamphlet just issued by the Adams Mfg. Co., in which they compare their Igranic metallic dimmer with the liquid dimmer, in opposite columns. On the points of safety construction, size, interlocking, upkeep, installation and lighting effects they make out a good case for the metallic dimmer. This is practically iron clad, and it can be installed to occupy a minimum of space both in regard to the moving contacts and the arrangement of the connecting cables. The resistances are enamel embedded, and they can be divided into a large number of steps so as to obtain almost imperceptible degrees of change in the strength of the light. The resistance is practically fireproof, so that it can be installed close to the operator without danger. The booklet is interesting from a comparative point of view, and should be in the hands of every theatre manager.

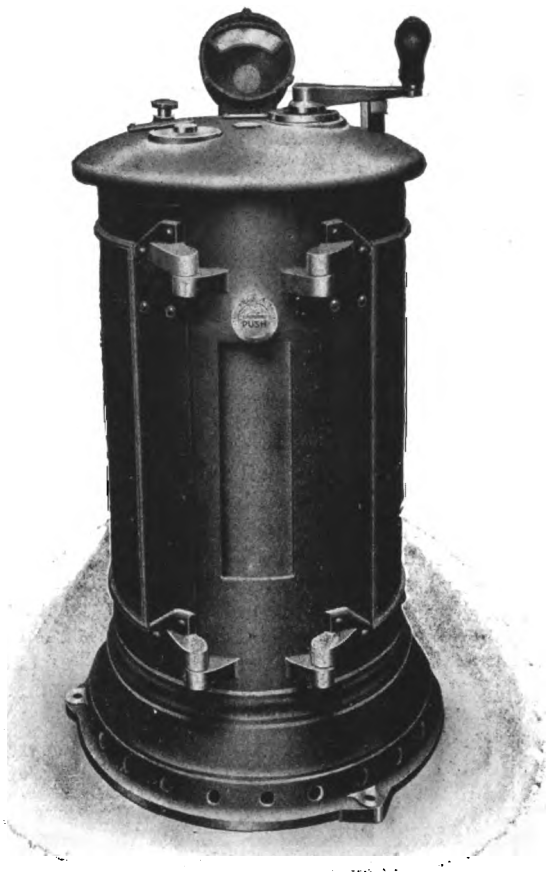
THE "EOA" CONTROL PILLAR.

Motor control panels do not always prove satisfactory in actual practice where the service is at all severe. For certain duties the flat type of starter has been replaced by the barrel or drum type controller, owing to the unreliability of the former on heavy duties. The "EOA" control pillar has been designed as a substitute for the ordinary motor control panel. It contains the necessary apparatus for starting, regulating and protecting the motor against overload and interruption of the supply. It consists of: (1) D.P. overload and no-voltage circuit-breaker, (2) drum type starter, (3) shunt regulator for variable speed motors, (4) resistances for starter and shunt regulator, (5) D.P. switch fuses, all enclosed in a weather-proof case and operated by one handle.

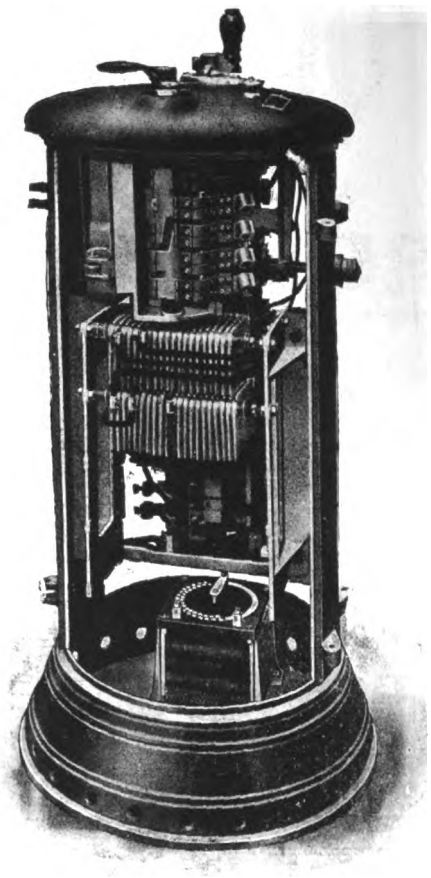
It is specially suitable for the control of motors operating printing presses, calendering machines, machine tools, or any machines which require to be frequently started and stopped. Where necessary, it can be arranged to release the circuit-breaker, and so stop the motor from distant points by means of push buttons, as is required for printing presses, &c. In starting, the press button on top-plate is pushed down and held down while handle is moved slowly to the running position. Should the button be released before this position is reached, the circuit-breaker will open, but after this point, and when



"EOA" Control Pillar, closed.

returning handle to "off" position, the button need not be touched. Further movement of the handle, after reaching the running position, inserts resistance in the shunt field, and speeds up the motor. The control pillar is fool-proof, and any attempt to open the doors while the motor is running releases the breaker and stops the motor.

The barrel consists of cast-iron spiders mounted on but insulated from a steel spindle. A ball thrust bearing is provided, which takes the weight of the barrel, thus ensuring ease of operation and preventing wear of the seating which would otherwise cause the contacts to get out of alignment with the fingers. The contacts are of hard-drawn copper, screwed to the barrel, and easily and cheaply replaced. The fingers are of hard-drawn copper, carried by laminated steel springs and connected to the terminals by flexible copper leads. The springs carry practically no current, and consequently retain their elasticity, even after heavy overloads. These springs are fixed to brass finger brackets, which are insulated from the finger bar by mica.



The "EOA" Control Pillar, open, showing Starting Resistance and Shunt Regulator.

A double-pole circuit-breaker is provided and is fitted with both overload and no-voltage releases. It is so interlocked with the main barrel that when it is opened the starting barrel has to be brought to the "off" position before the motor can be re-started. The starting resistance is contained in the same carcase. The standard resistance is one-minute rated, and is for starting only. A push button is fitted for stopping the motor at any position of the starting handle. This push button releases the no-voltage coil, and then mechanically operates the circuit-breaker, so that, should the latter tend to stick, it is forced open. The control pillar can be made reversible, the reversing barrel being operated by a separate lever. This reversing barrel is, however, interlocked with the starting barrel so that the connections can only be changed over when the starting handle is in the "off" position. A shunt regulator can be provided in the same case, and, being operated by the same handle as the starting barrel, all possibility of the motor being started under light field is avoided. Double-pole fuses are fitted inside the carcase. The pillar is of substantial construction throughout, and contains no wood or other combustible material. The "EOA" pillar is made in four sizes to deal with motors ranging from 5 to 150 H.P., there being three voltages per size of 115, 230 and 460 volts.

HYTHE ROAD, WILLESDEN, LONDON, N.W.

IFS AND QUERIES.

For Mr. A. M. Taylor: To boost or not to boost, that is the question? Ay, there's the cell.

Why all this talk about foreign finance and its application to our industries? Surely we can turn the corner without artificial banking?

We have the Old Ferrantians, the Old Faradians, the Batti-Wallahs, the Generators, and the Dynamicables. What next? The Exciters, the Boosters and finally the Condensers?

Will the suggested lunar-tidal electric power scheme prove ultimately to be all moonshine?

Will the new Thames auto-tumbler successfully walk the tight-rope of competition?

AN ANSWERED QUERY.

In our issue of December 30, 1910, we asked: "Will Mr. Ferranti again occupy the Presidential Chair of the Inst.E.E.? If not why not?" Enough said.

(See larger Advt. last week.)

WESTINGHOUSE LOOM MOTORS.

Considerable interest has been taken recently in the individual driving of looms by small electric motors specially designed for high efficiency. Some few months ago, the British Westinghouse Co. secured an order for the equipment of a weaving shed on these lines from Messrs. Edward Hibbert & Co., of Hyde, through their consulting engineer, Mr. Robert Blackmore, of Stalybridge. This installation is now at work, and we understand that the looms are running much quicker and steadier than they did under the ordinary system, and the operatives are well satisfied with the alteration. The motors are so arranged as to use a short belt, and the drive ensures smoothness of running and prevents slips.

ALLEN WEST CONTROLLERS.

A large variety of switchgear in the shape of motor starters, controllers and resistance grids is made by Allen West & Co., Lewes-road, Brighton. In a new pamphlet and folder which the firm has just issued are to be found a number of illustrated particulars of these devices. Among these we notice a self-aligning fuse which has sundry novel features. The fixed contact jaws for the fuse are of the rigid type, and the contacts in the ends of the porcelain handle are capable of adjusting themselves to the surfaces of the fixed contacts. There is ample ventilation provided by the use of a hard asbestos tube and this ensures that the handle will always remain cool under working conditions. There is no expansion of the fuse contacts, so that the porcelain will not burst, as frequently happens when cemented ends are employed. The list referred to also contains details of an interesting line of liquid controllers and drum type controllers, the latter for crane service. The list has been well arranged and is carefully printed.

IMPROVED TESTING SETS.

Users of multi-range instruments will have experienced the difficulty of ensuring that the winding is not "burnt out" through the application of a high pressure to one of the lower ranges of the instrument. A fruitful source of danger in this respect lies in the plug and socket arrangement frequently employed as a means of changing from one range to another. Even with the arrangement formerly adopted by Messrs. Everett, Edgcumbe & Co., namely, to provide a separate ebonite cover terminal for each range, whereby the risk was minimised, there was always a chance that accidental contact might be made with the wrong terminal.

In their latest sets, herewith illustrated, this danger has been eliminated by the provision of a circular switch, and any required range can be instantly selected. Moreover, this switch is so arranged that it has always to be brought back to the position corresponding with the highest range before the case of the instrument can be closed. By this means it is ensured that the highest range is the one left in circuit and a "burn out" is almost impossible.

FIG. 1.—MODEL 1, COMBINED INSTRUMENT.

Figs. 1, 2 and 3 show three distinct types of testing sets, the first being known as Model 1, which consists of two moving coil instruments, an ammeter and a voltmeter, each provided with a number of ranges. Model 2. (Fig. 2) consists of a single instrument fitted with a change-over switch, by which it can be instantly used either as a voltmeter or an ammeter, as may be required. This change-over is accompanied by an ingenious switch, which is entirely contained within the instrument, and is actuated by two ebonite knobs marked in "amperes" and "volts" respectively. The exposed switches so often provided for the purpose of changing from the current to the pressure measurements, and vice versa, are a source of constant danger, and should certainly never be used by any unskilled person. Model 3 (Fig. 3) consists, as will be seen, of two distinct instruments in one case, and is of Messrs. Everett, Edgcumbe & Co.'s "Universal" pattern of moving iron.

One of the main features of these instruments is that for alternating-current work the indications are entirely unaffected by change of frequency and, which is often quite as important, of wave form also; as a consequence the same instrument can at any time be used with very fair accuracy for continuous-current measurements, should this be desired.

FIG. 2.—MODEL 2, SINGLE INSTRUMENT WITH CHANGE OVER SWITCH.

The dimensions of these instruments, complete with current shunts and pressure resistances, are as follows:—Model 1, $13 \times 8\frac{1}{4} \times 5\frac{1}{2}$ in.; model 2, $8 \times 7 \times 5\frac{1}{4}$ in.; model 3, $13 \times 8\frac{1}{4}$ [illegible]. All three are provided with the above-mentioned multi-range switches for changing the pressure ranges. This makes them practically "fool-proof."

As the result of experience with various forms of finish for cases, Messrs. Everett, Edgcumbe & Co. have adopted the practical course of having the instruments in plain unpolished light oak cases.

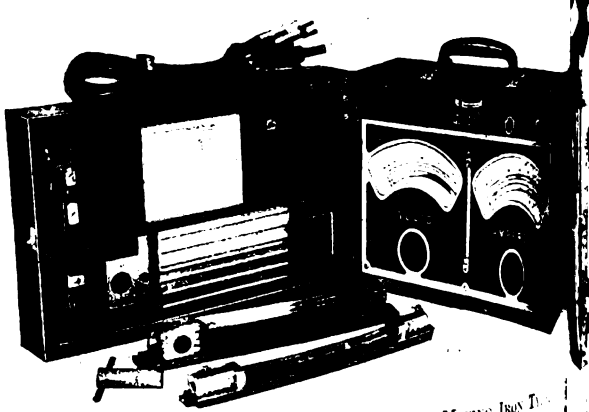

FIG. 3.—MODEL 3, COMBINED INSTRUMENT, MOVING IRON TYPE.

Of the various other features possessed by these instruments we need hardly speak, as they are already well known to engineers. Each instrument is provided with an external zero adjustment, with rubber shock absorbers, with knife edge pointers and anti-parallax mirrors, and last, but by no means least, with an efficient damping arrangement.

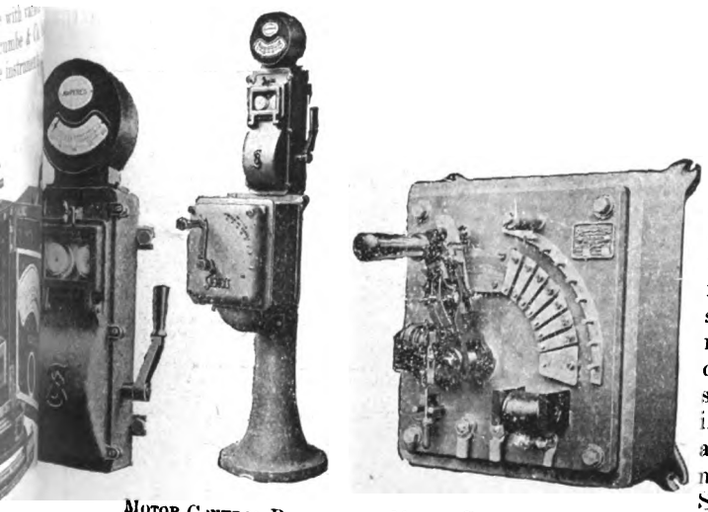
SWITCHBOXES AND MOTOR CONTROL PANELS.

We illustrate herewith some compact types of switchboxes and motor control panels. The former will be seen to consist of a cast-iron case and contain a double or triple-pole switch and cartridge fuses, mounted on porcelain. An ammeter



Motor Control Panels and Motor Starter.

can be supplied, if desired, mounted on the top of the case. All joints are made so that the box is completely weatherproof and the complete apparatus is solid in construction. The window for the fuses is hinged and is so interlocked in the 100-ampere size, and above, that it cannot be opened whilst the switch is closed and, conversely, the switch cannot be closed while the window is open. The fuses are of the now well-known "Zed" type, provided with an indicating device which shows at a glance when a fuse has blown. All live parts are completely enclosed, making it impossible to receive a shock accidentally when replacing a cartridge and no "arcing" or "flashing" occurs when a fuse burns out.

The switch has a quick-break action and each pole is mounted on a separate porcelain. The boxes are so arranged that 2, 4 or 6 cables can be led into the box from above or below, except when an ammeter is used, in which case only two cables can be led in from the top. The boxes are stocked undrilled and are drilled to suit customers' requirements and cable glands and packing can be supplied.

In the motor starters the contacts are renewable and of ample area and cross section, and overload and no-voltage release are fitted. The centre spindle is provided with a ratchet and the overload release with a pawl, and these two come into operation if the motor is switched on too rapidly, and prevent further movement of the brush. A patent step-by-step slow motion gear can be fitted to these starters. In this gear the switch is moved sharply from one contact to the next, but retained at each step for a short time to enable the motor to come up to speed. The advantages of such a device as this scarcely need to be pointed out. This gear is shown in the illustration. The motor control panels, mentioned above, are a combination of the switchbox and starter already described, mounted on a cast-iron pillar. These controllers are made by Siemens Bros. Dynamo Works, who specialise in motor-control gear of every description.

MORE TANTALITING.

We reproduce two untouched photographs illustrating the interior of a church illuminated by gas and electricity respectively. The clear outline of the architectural details of the church interior is a testimony to the efficiency of the electric lighting which was, in this case, accomplished by Siemens "Onewatt" lamps. Apart from the fact of a better illumination, the actual lighting bill has been considerably less than with gas, whilst money will be saved in the cost of redecoration and cleaning. These advantages, together with the fact that the initial cost of high candle-power "Onewatt" lamps is now lower, should encourage similar installations.

Messrs. Siemens Bros. Dynamo Works (Ltd.) inform us that they are now placing upon the market a further range of "Tantalum" candle lamps. Hitherto these lamps have not been supplied in higher voltages than 60, in 5 and 10 c.p. sizes, but the new types will be supplied in 10 and 16 c.p. for 70 to 120 volt circuits. The filaments will be of drawn tantalum and the efficiency will be precisely the same as that of the ordinary "Tantalum" lamps at present on the market. These lamps will be listed at the price of 2s. 9d. each, and it is anticipated that there will be a large demand for series burning candelabra fittings on high voltage circuits. The lamps are approximately 5 in. long and $1\frac{7}{8}$ in. in diameter.

MINE SIGNALLING AND TELEPHONY.

Amongst the accessories of general interest particular to mining work should certainly be mentioned telephones, bells, signalling keys, relays, generators and exploders. In the latest types of mining telephones the care is of cast iron and carries the watertight receiver, induction coil, and spring jacks, mounted securely on it, while the cast cover, with the speaking transmitter fitted to it, is secured to the base by means of set screws. The cover is recessed for fitting to the case, and the whole station is made gas and waterproof by means of a packing cord soaked in paraffin wax fitted into the recess in the cover.

On the left of the case is the ear-piece for the listener, attached to the case by a length of flexible metal tubing, which, whilst adding to the comfort of the operator when listening, still conforms to the necessary substantial character of the station. On the right is the ringing and speaking key used by the operator, which, passing through the case, operates the necessary springs for the ringing and speaking connections, and is kept watertight by means of a packing gland and socket. In an installation using this type of instrument, the main or central set, including the calling indicator and central battery, would be fitted at the pit head, whilst other sets would be fitted at the different galleries or working levels. The indicator box consists of a cast-iron case carrying the apparatus, and the cover carrying the three indicators and three bells. The indicator box is fitted with three visual indicators and bells, so that while the main set is speaking to another set the remaining stations can ring up and draw attention at the main set without interrupting the conversation. Connections to the indicator and terminal box are brought through packing glands at the bottom, so that the whole set can be kept watertight. Each of these stations is fitted with a signalling bell, and terminals are provided for an extension bell to be fitted away from the station should it be required. A station of similar design, but fitted with hand generator for magneto working, can be used equally well if desired.

Mention may now be made of an installation for an alarm circuit for a constant water supply, or to show the fall of water in a working. It comprises a watertight key with a water buoy attachment, and alarm bell of the watertight iron bell type, together with a relay and necessary battery. Upon the water falling, the buoy falls and operates the pull, connecting the circuit through the bell and battery, when the alarm bell rings. The attendant's attention is drawn to the fact of low water level, and he presses a key which breaks the bell circuit and puts the battery through a relay until the water rises, when the relay armature is released and the apparatus is re-set. A more elaborate system of signalling may be used when it is required to maintain a constant level, or to signal when a rise or fall takes place. A double battery is essential in this case, and is connected up, as shown, with an additional polarised indicator, in circuit, the mining pull being also fitted with Morse contacts. Upon the water level rising, the alarm circuit is completed and the bell rings, whilst at the same time the coils of the indicator are energised by the current in a forward direction, and the armature is attracted so that the indicator registers a high level. For a fall in the water level the current through the indicator is reversed, and a low level indication is made. The alarm and restoring is done in a similar manner

as in the first instance. Installations of a similar nature can be designed and carried out to suit individual requirements for any type of work requiring constant supervision of the water supply, and will be found a great advantage owing to their low cost and certainty of action.

One of the latest types of signalling installations for a mine winding gear, with visual and oral signals, is shown in Fig. 1. The main set—at the pit head, for example—consists of two watertight keys, together with a large pedestal indicator, whilst the bank and different levels are each equipped with one watertight iron bell with single stroke action, one mining pull, one simple alarm switch, and a junction box of simple pattern but of watertight construction. This system is purely a signal system with code ringing for the signals, the signals from any one station being heard at all the others, as the bells are connected in series. Should an operator at one level desire to signal the winding room and bank, he simply pulls his mining key, and at each pull the bell gives one stroke; the operator can thus give the code ring he desires, and this is transmitted to all the other stations, so that they know according to the code who is speaking and what is wanted, and do not interfere until the line is clear. These signals are transmitted to the winding room pedestal indicator, and here the bell moves in unison, thus giving the oral signal required. The indicator has a face like a clock, with a large centre and five small circles outside, each with a lamp behind, one for each outside set of apparatus—that is, each level and bank. Immediately the level rings up, besides the bell ringing, the particular small lamp for that level lights up as well, whilst the centre of the indicator is also illuminated. The lamps remain alight, and as the level rings the code, so for each ring, the mechanism of the indicator causes a dash to appear on the centre face of the indicator; thus for three short rings three short dashes are obtained, and for three long rings three long dashes, these dashes remaining upon the face of the indicator whose face is lighted by the lamp behind, thus giving a certain index of what calls have been transmitted, until the operator in the winding room answers the call, whilst at the same time the small indicator lamp round the face shows the origin of the call. The winding room then answers by ringing back the same call on their mining pull, and this answer is transmitted back to all stations. The calling station then signals his call as correct, and the winding room re-sets the indicator by simply pulling his re-setting key RK, which breaks the relay circuits that keep the lamps glowing, and the lamps in consequence go out. Thus the operator in the winding room gets the signals from the bell and also sees them down in black and white, whilst the levels know they are not being attended to unless they get their ring back again, when they give the "all right" signal and everything proceeds. By this means it is claimed to be practically impossible for mistakes and accidents to occur, and the indicator system speaks for itself as regards utility and certainty of operation. The additional alarm switch provided at each level

is for the purpose of giving a special alarm in time of danger, and is simply switched over by the operator at the level before he rings, when a special danger lamp, A, in addition to the other lamps, lights up on the face of the indicator, and the signals then appear in the ordinary way. The diagram of connections for this system of signalling is shown in Fig. 2.

Another very useful piece of apparatus for mining work is the mining exploder. It consists of a small hand generator in a portable case, and is fitted with two line terminals, the generators being made in three different sizes. A bell for use in conjunction with this set, or for working direct from alternate current mains, is the polarised bell. It is of similar design to

A USEFUL MINING SWITCHGEAR PUBLICATION.

Many manufacturers fail to take advantage of the opportunity which is frequently presented to them of making the publications describing their standard products of permanent value and utility. A publication just issued by the British Westinghouse Co. is noteworthy as an example of how attention can be directed to the latest products of a company, while at the same time a quantity of useful information is also supplied. The publication in question is entitled "Electricity in Mines," and it is mainly devoted to the Report of the Committee re Electricity in Mines, the proposed new special rules, the proposed official notification forms, and the memorandum of the Committee on the proposed new rules. As a supplement to this matter there are 16 pages of carefully prepared and well illustrated descriptions of the latest pattern of Westinghouse switchgear for mine service. The articles in our Special Mining Section this week will be found to contain some account of this new switchgear, but limitations of space quite naturally prevent us going as fully into the subject as does the pamphlet before us. At the same time, the issue of the publication at the present moment, coinciding as it does with our Special Mining Number, will certainly increase the interest which must attach to its perusal. We can only recommend every mining electrical engineer who has not already received a copy of this interesting piece of literature to make application to the company for the same.

NICLAUSSE AUTOMATIC STOKERS.

In a previous issue we published some particulars of the Niclausse boiler. We now gather that the British Niclausse Boiler Co. have ready a catalogue describing their automatic mechanical stoker. The elements of this stoker consist of two steel plates or bearers about 8 ft. long, bolted together at the end with distance pieces, leaving an inch wide channel between the two plates. Each element carries a number of cast-iron stepped firebars about 6 in. wide. The tang of the bars is inserted in the groove between the two plates, and they are kept in position by toggle joints. The grate is built up of a number of these elements, according to the width desired, and sufficient space is left for air passages without fouling; the elements are set with an inclination of about 9 deg. to the horizontal. The elements rest on small rollers at the front and back, and are reciprocated by cams on a shaft placed at the front outside the boiler. Each element is reciprocated alternately, and every few seconds all the elements are simultaneously moved from front to back. This action mixes the fuel, spreads it evenly over the grate, prevents air holes, detaches the clinker and works the burnt products to the back of the grate.

The main frame of the stoker is independent of the boiler, and it may be withdrawn so as to leave a space under the tubes for the inspection of the brickwork.

The fire bars at the front of the grate do not admit any air, and act as a dead plate. The next set of bars forward are of extra hard cast iron, and have air passages between them. They are short in length and the upper faces are stepped. Only a small surface of the bar is in actual contact with the fire, but there is a large surface exposed to the cool air ascending from the ashpit. This prevents burning of the bars and ensures against the formation of clinker.

Natural, induced or forced draught can be used with this stoker, but the latter is preferable, because combustion can be made independent of atmospheric influences, the flues or the height of the chimney.

THE FOSTER DIMMER.

Some weeks ago we asked in our query column what the name of the next dimmer switch would be. The title above supplies the answer. The switch is made by the Foster Engineering Co. in two types, one for direct-current and the other for alternating-current circuits. The switch is specially recommended for use in connection with metal lamps, and the following table shows the current economy at various positions of the switch :—

Stop.	Per cent. saving.	Watts used.
1	Full on	200·0
2	16·0	168·0
3	48·5	103·0
4	82·0	36·0
5	95·8	8·4
6	97·8	4·4

The switch is connected to a variable choke coil, from which a number of tappings are brought out to the contacts of a multipoint switch. The apparatus is enclosed in an iron cover and occupies a minimum of space.

A CROMPTON CONVERSAZIONE.

A pleasant evening was spent last Friday by the members of the Arc Works Engineering Society, Chelmsford. Col. R. E. Crompton, C.B., was in the chair, and a good programme of music and song was gone through. The Colonel presented prizes to both the pupils and apprentices for Papers read during the session. They were all of equal value and presented by Crompton & Co. The recipients were (pupils) E. A. Boyd for a Paper on "Synchronous and Asynchronous Converting Machinery," and Lieut. Mehmed Ichssan, of the Turkish Navy, for "Oil Fuel for Marine Use": the lieutenant is evidently a popular man judging by the ovation he received. The apprentices were E. Hughes ("Electricity as a Motive Power in Coal Mines"), and S. P. Trounson ("Gold Mining on the Rand"). In handing the prizes to the above gentlemen the Colonel addressed a few appropriate words to each.

The entertainment was contributed mainly by the Works staff, and included quartettes by Messrs. Parker, Brown, Auger and Gainsborough; the last-named also rendered several songs with effect. Mr. G. L. Williamson has considerable command of the 'cello and Mr. C. Lucy was in form as a dramatic reciter; Mr. Phillips was the humorous songster of the evening, and had to respond to repeated calls, and Mr. W. G. Smith, in addition to presiding at the piano, displayed his ability as an accomplished pianist. The party included a number of visitors from London, of whom Mr. T. E. Gatehouse contributed to the programme. During the interval an inspection was made of a number of electrical experiments set out by the students.

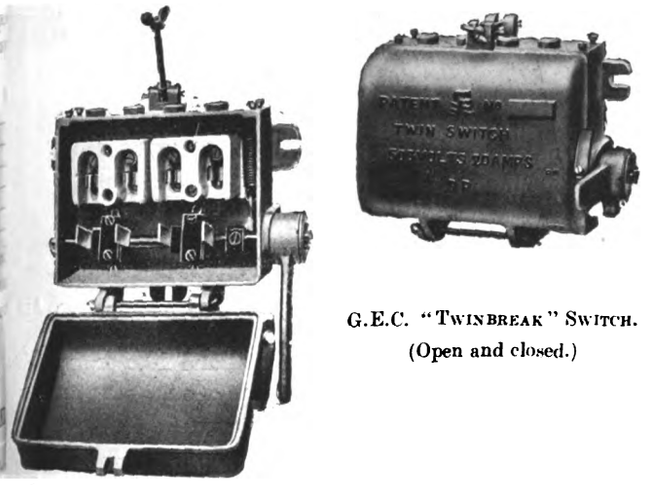
We had the pleasure of attending at this delightful fete gathering of Cromptonians, and while in Chelmsford had an

Digitized by Google

opportunity of a walk through the shops with Mr. Macfarlane, the genial co-designer, with Mr. Burge, of the now well-known C.M.B. converter. The dynamo shops showed signs of plenty of work in both a.c. and d.c. machines. Mr. Macfarlane pointed out what an influence efficient ventilation had had on the size of modern dynamo electric plant, and in particular, with the up-to-date Crompton machines. We were particularly struck by the extremely small diameter of the armatures for quite large outputs, these looking almost ridiculously small by the side of the old medium-speed dynamos which furnish power for the driving and lighting of Arc works. By the use of thinner core plates and by adopting what is known as the "up and down" placing of the plates, this being simply the use of adjacent plates of slightly different diameter, a greater radiation surface for the heat is obtained. The ends of the windings also admit of the free passage of air between them from the interior of the armature.

"TWINBREAK" IRONCLAD SWITCH.

In this switch both contacts and poles open and close simultaneously, thus meeting a demand for an ironclad switch in which the hinge does not form one contact, but in which two separate breaks per pole are used. The break is long and the contacts are entirely surrounded by porcelain, making a short circuit between opposite poles practically impossible. Mica



G.E.C. "TWINBREAK" SWITCH.
(Open and closed.)

under compression is used as insulation between the metal parts carrying current and earth. The switch complies with the Home Office Regulations as to earthing terminals for the case, and an indicator is provided for denoting whether the switch is open or closed. It is impossible to only partially open the switch, whilst at the same time, the case cannot be opened until the switch itself is open. The handle does not project through a slot in the cover and it is not possible to get a shock due to the handle being accidentally alive nor to be burned due to flame coming through the slot. The spring which gives the quick action to the break operates through a curved link so constructed that when the contact is full home it is just over the dead centre, consequently there is no tendency for the switch to spontaneously pull off and open circuit. On first pulling forward the handle, the spring controlling this is brought into tension; and should the switch not be opened, the handle immediately flies back to its first position. The maximum tension of operating spring is reached just at the point when the switch blade leaves the contact, so that the break is very rapid. The switch is being made and marketed by the General Electric Co.

EXCELLO
FLAME ARC WITH UNIQUE
TWO YEARS' WARRANTY

THE MILLIWATT LAMP.

Since the publication of our last note on the Milliwatt lamp another remarkable instance of its durability has been brought to our notice by the makers. A case of lamps was being taken from the works by monoplane carrier to a customer in the Midlands when for some unexplained reason the aviator found that the case had come unshipped. He saw it hanging by its packing cord from the frame of the machine, and one by one the 100 lamps were shaken out of the case, falling in their cartons 1,000 ft. to the ground below. The aviator continued on his course until the last lamp had been dislodged by vibration, and finally the case itself sped earthwards, falling into a hen roost and causing much consternation among the feathered inmates. As the aeroplane was travelling at a high speed the 100 lamps were distributed over a wide tract of country. The makers, however, now write informing us that the 100th lamp has been traced and recovered. They assure us, without blushing (though they write on pink note paper), that none of the lamps were damaged, and they are all burning brightly as if nothing had happened. The 13th lamp (doubtless with a view to maintaining the reputation of the number for ill luck) suffered most out of the consignment, for the stem supporting the filament was snapped by the shock of the fall. The filaments themselves (the lamp was 250 volts 100 c.p.) refused to follow suit, and glowed merrily when the lamp was carefully placed in a holder and switched on. We understand that this size of lamp will be known in future as the Aerowatt.

IFS AND QUERIES.

If a profit could only be made on the sale of Coronation illuminating material.

If Mr. Merz ran the "Daily Mail."

Has the Institution organised a trip to Constantinople yet, with calls at Paris and Vienna en route?

What is the consumption of standard bread among the members of municipal electricity committees?

Is Mr. Christie preparing special triple concentric sticks of Brighton rock for the I.M.E.A. members to take home after the convention?

Will the G.E.R. run a late special to town for the Arc Works dinner and smoker next year, or will C. & Co. short-circuit the railway by C.M.B. monoplanes?

Will the N.E.M.A. take for the subject of its next discussion the electrical aspect of the Aliens Bill?

Queen Mary I. said that when she died the word Calais would be graven on her heart; will disappointed electrical engineers also notify their expectations in similar circumstances?

REAVELL COMPRESSORS AND MINING HOISTS.

Among the compressed air plant in use in underground mines the Reavell quadruplex compressor is now very well known among mining engineers. The compressor has four cylinders arranged in an annular casing. This casing forms a water jacket which surrounds all the cylinders. There is also a circumferential belt running round the casing, into which each cylinder delivers its air. The water, in addition to surrounding the cylinder bodies, has access to the cylinder heads, enveloping that part in which the valves are situated, and also the pilot cylinders. It will thus be seen that an excellent cooling effect is obtained which extracts a correspondingly large amount of heat from the air during compression, and therefore results in a very low power consumption for driving the machine.

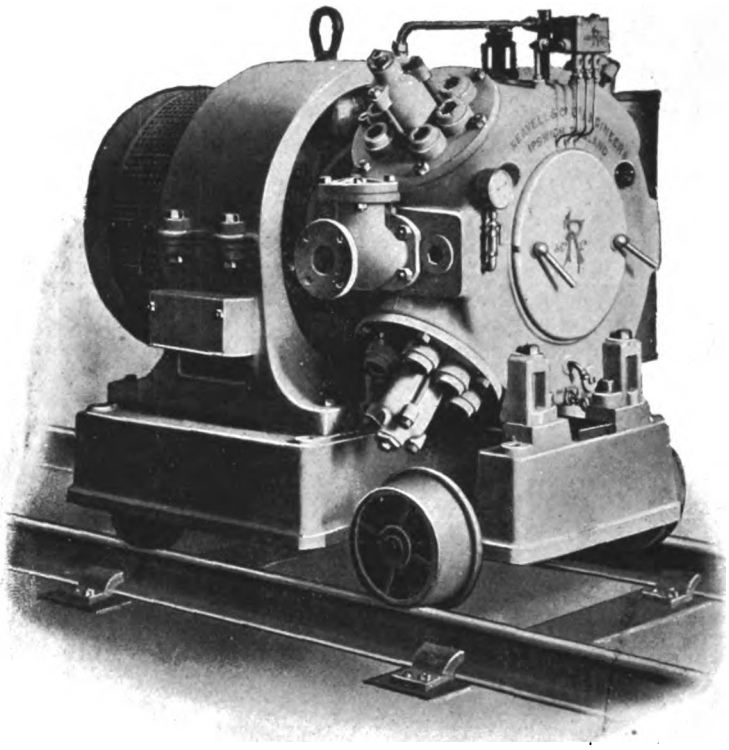

FIG. 1.—GENERAL VIEW OF PORTABLE COMPRESSOR.

All the four pistons are actuated by connecting rods, bearing upon a crankpin common to all. Air is admitted to the cylinders through ports arranged in the connecting rod gudgeons, and corresponding ports in the pistons which are opened and closed by the axial motion of the gudgeons. This does away with the need for spring loaded suction valves, and effects, it is claimed, a gain in volumetric efficiency of at least 5 per cent., as compared with compressors having spring loaded suction valves. The arrangement of the four cylinders also results, we understand, in an even turning moment, thus rendering the machine quite suitable for electric driving, and especially for direct coupling to electric motors. Another great advantage of the machine is the fact that all the pistons and connecting rods can be withdrawn in a few minutes, by simply removing the tap bolt fixed in the end of the crankpin. As an example of this class of plant we may mention a direct coupled electrically-driven machine, which is arranged upon wheels so as to be run on a tram line. This machine is illustrated in Fig. 1. Gear-driven compressors too are manufactured in large numbers, and can be arranged to run on tram-lines when necessary.

Messrs. Reavell & Co. also manufacture a compact little motor-driven compressor suitable for use in collieries, and other power stations, for the purpose of blowing dust from switch-gear, armatures, &c., which they term their "sub-station" Cleaning Set.

The same firm manufacture a useful mining hoist (*see* Fig. 2). This is driven by a pneumatic engine constructed on a similar principle to the compressor, and so arranged that it is entirely without valves. A winding drum is arranged through the centre of which the engine crankshaft passes, and actuates the epicyclic gearing contained in a casing at the outer side of the drum, thus making the whole extremely compact, while everything being enclosed danger of breakage through falling rubbish, &c., is avoided. The hoist is shown mounted on a pillar, and can be arranged for any position and at any angle. One of the feet of the pillar is adjustable, so as to render the hoist capable of being wedged between roof and floor or any other convenient position.

FIG. 2.—MINING AIR H[illegible]

THE REDUCTION OF COAL DUST IN MINES.

The danger of coal dust in mines is a question which has been engaging the attention of mining experts for some considerable time, and it is now generally acknowledged that when allowed

to accumulate in the workings, it becomes a serious menace to the safety of the personnel and plant on account of its extreme liability to explode. In fact, it is considered that several recent colliery explosions have been due to this cause, and in the proposed new regulations for the Coal Mining Industry, which are shortly to come before Parliament, there is a clause which reads as follows :—" Arrangements shall be made to

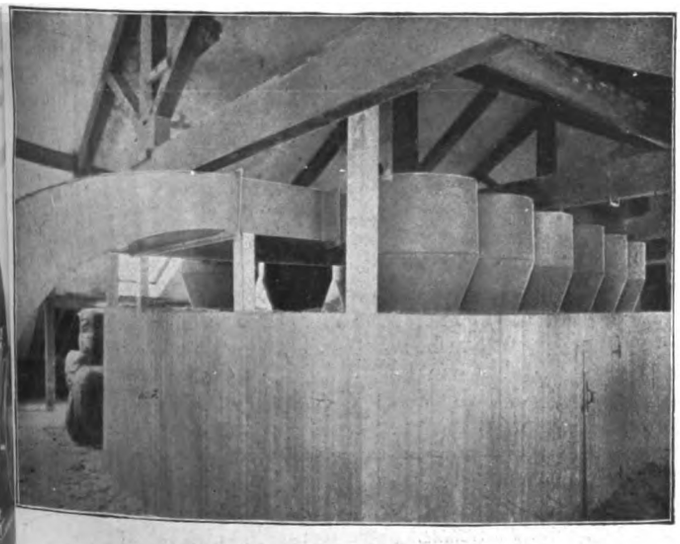

FIG. 2.—SEPARATOR PLANT.

prevent as far as possible coal dust from the screening entering the down cast shaft."

Down in the mine itself the dust question is a difficult subject to handle, on account of the dust arising at so many points in contradistinction to the conditions on the surface where this is not the case. The screens and tipplers are undoubtedly responsible for creating a large proportion of the dust on the surface, and owing to their close proximity to the pit mouth, this dust is drawn into the workings by the action of the

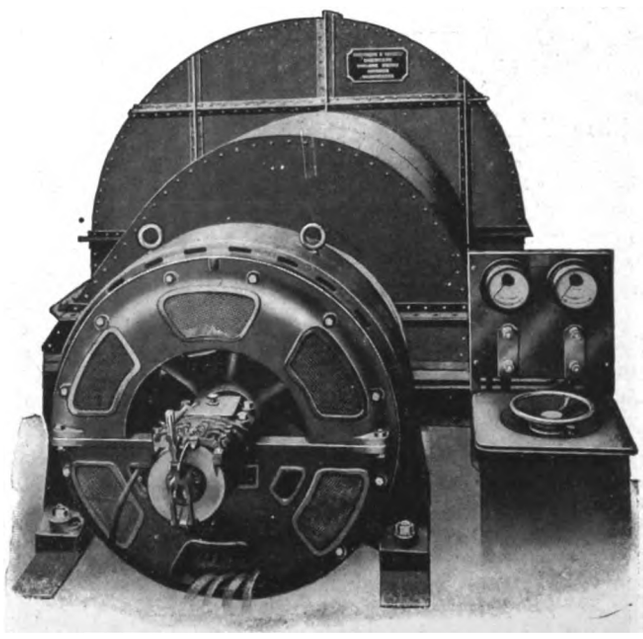

FIG. 3.—INDUCED DRAUGHT CYCLONE FAN.

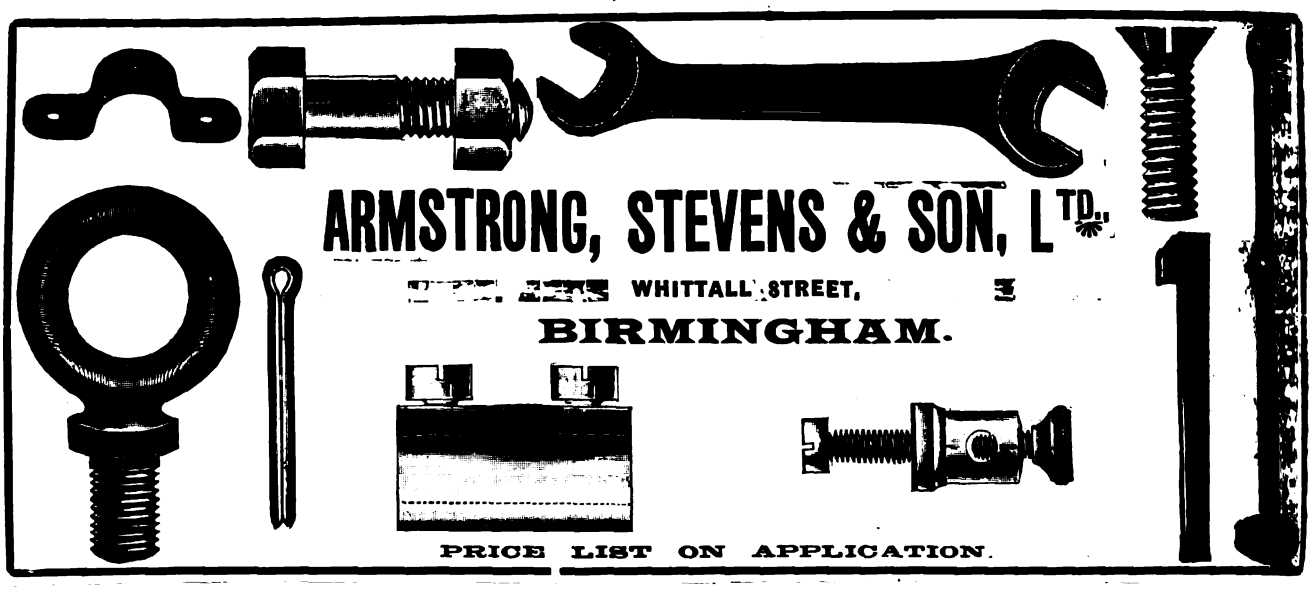
ventilating fans. To overcome this difficulty the Cyclone dust collecting plant has lately been introduced by Messrs. Matthews & Yates, Ltd., who claim to have installed the first plant for this purpose.

A typical plant consists of an electrically-driven Cyclone exhauster, and a battery of the firm's lately patented Cyclone

Digitized by Google



separators, such as is shown in Figs. 1 and 2, which may be fixed in any convenient position. The suction side of the fan is then connected with the screens, &c., by means of hoppers, hoods and trunking, through which the fans draw the dust-laden air, delivering it into the separators, where by centrifugal action, the dust is caused to fall into suitable receptacles, while the air escapes at the top. Fig 3 will give a general idea of the plant.

The advantages of such a plant are twofold; first, in preventing the coal dust from being drawn down the shaft into the workings by the ventilating fans, and secondly from a commercial point of view, as the dust collected when kept dry is a saleable article, and one that will find a ready market.

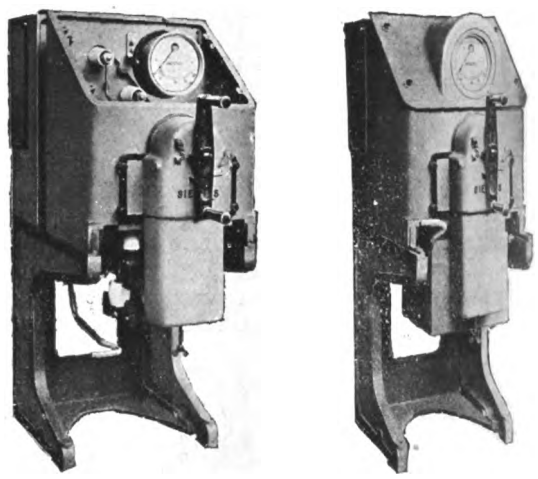
The Cyclone blower and exhauster (Fig. 2) is also highly suitable for mine ventilation, not only as the main ventilator, usually on the pit brow, but also when, coupled to electric motors, it can be used as an auxiliary to the main fan, for supplying ventilation to remote workings. Fig. 3 shows a combined motor-driven induced-draught set. A plant of this description guarantees a plentiful supply of steam, an absence of black smoke, and enables the user to burn the refuse from the coal.

MINING PILLARS.

The mining pillars illustrated are designed for three-phase circuits up to 300 amperes at 3,300 volts. The frame-work and outer casing of the pillar are of cast iron, the whole being arranged for floor fixing. Various combinations of apparatus are possible, but in each case two triple-pole isolating switches and a triple-pole automatically operated oil switch are included.

The oil switch may be provided with one, two or three over-load releases with or without "air vane" time limits, or a similar number of no-voltage releases or any combination of these not exceeding three releases to each switch. If desired, the releases can be arranged for operation from an auxiliary circuit. These pillars can be fitted with a special buffer resistance to prevent an abnormal rush of current when the switch is first closed. The isolating switch is operated by the movement of a carriage carrying the oil switch and other apparatus.

The oil switch is of the "free handle" type, and it is impossible to withdraw the carriage unless the switch is in the "off" position. The oil tank or the cover cannot be removed until the carriage has been withdrawn, and the carriage cannot be pushed in to close the isolating switches until the tank and the cover have been replaced and the oil switch put into the "off" position. All live parts are completely protected from accidental contact. For pressures above 650 volts the no-voltage coil and voltmeter, when fitted, are operated through a pressure transformer mounted below the cover, which is then of special design. The pillars can be supplied with ammeter and voltmeter if required.



MINING PILLAR WITH AMMETER.
With cover removed. With cover on.

These pillars can be used singly or combined in any required number to form a totally-enclosed switchboard, in which case 'bus bars are arranged in the upper portion of the pillars and fixed in such a way as to prevent accidental contact. The cables can be led in from the top or bottom, and suitable bifurcating boxes can be supplied for this purpose. If preferred, porcelain bushes can be supplied for single-core cable. The pillars are made by Siemens Bros. Dynamo Works, who will furnish full details and prices on request.

THE ELECTRICIAN COMMERCIAL AND INDUSTRIAL SUPPLEMENT.

C. & I. Supplement No. 85.] MAY 19, 1911. [Gratis to Subscribers.

ELECTRIC PULLEY BLOCKS.

The electric lifting appliance in the shape of the massive crane is a recognised institution in almost every sphere of industry. It is an accepted fact, and to such an extent that the claims of the smaller electric lifting device are often overlooked. The electric pulley block and small electric runway is of immense value in every branch of engineering trade and commercial work. We illustrate two views of a handy pulley block which is self contained, and can be hung on a crane hook or any other convenient support, and operated from a local light or power circuit. The block takes up no more room than a hand pulley block, and the load hook hangs in a vertical plane with the suspension hook whether loaded or not. We understand that the saving in labour quickly pays for the cost of the electric pulley block.

The pulley block is made in standard sizes for loads from 10 cwt. to 5 tons, and the motor can be supplied for d.c. or three-phase circuits. The block is silent in operation, and as will be seen from the illustrations is controlled from the floor level. The controller, motor gearing and chain wheels comprise a self-contained unit, and the operation of the controller is simplicity itself. These blocks are made by the Electric Pulley Block Co., 47, York-street, Westminster, London, S.W., and Messrs. A. W. Pocklington & Co., at the same address, are the sole selling agents. They also supply electric runways and overhead travelling cranes for use in specially cramped positions. They inform us that their lifting devices are widely used and appreciated, and they will be pleased to supply catalogues or other details on request.

The advantages of electric pulley blocks are evidently appreciated judging by the great variety of uses to which the above-mentioned pattern has been put. The makers have on hand a number of illustrations which depict actual installations of the device.

A NEW PUNKAH FAN.

The electrical operation of a punkah proved to be for some time a troublesome problem, principally because of the peculiar "flick" which was the speciality of the expert punkah puller, and which was difficult to reduce to mechanics. This "flick" practically gave the punkah its reputation as a cooling device, and until it could be faithfully reproduced the electrically-operated punkah was not considered worth its salt. We were given an opportunity last week of inspecting a new electric punkah which seems to fill the desired requirements and by simple and efficient means. The device in question was shown in operation at the London offices of Messrs. Hogan & Wardrop, who are well known as the agents for E.M.I. electric fans.

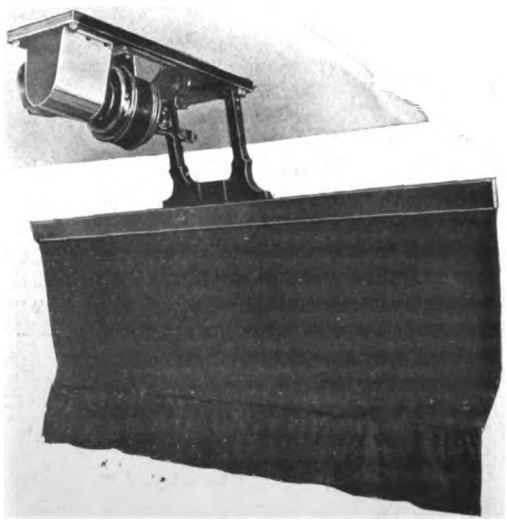

FIG. 1.—E.M.I. PUNKAH FAN.

A general view of the punkah is shown in Fig. 1, which illustrates the complete device as designed for ships' cabins, and also for use in residences, offices, &c., in tropical climates. It comprises a horizontal motor and a worm-reducing gear, both mounted complete on a substantial sole plate. The same plate carries the bearings in which the metal frame for the punkah is free to swing. This frame is mechanically and rigidly coupled by a connecting rod to a crank on the reduction gear of the motor. The rotation of this crank at a speed 12 times less than that of the motor causes the punkah to swing slowly from side to side. The flick is obtained by the slight hesitancy of the connecting rod in passing the dead centres of the crank. The effect is very real, and the resultant "puff" of air, far from being a draught, is quite pleasant to sit under. This, of course, is as it should be, because the "live" punkah gives just such a result.

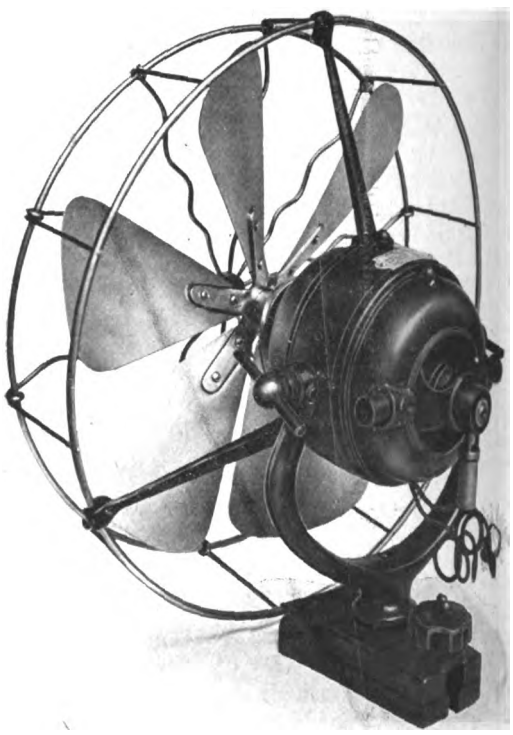

FIG. 2.—E.M.I. NEW SEASON'S FAN.

The motor can be supplied for both alternating-current and direct-current circuits, though for ship service only the latter would be used. It will be seen that the gear is completely enclosed, and both worm and wheel run in a continuous bath of graphite grease, which causes efficient lubrication and practically eliminates noise. We could not detect any sound above that of the soft purr of the motor itself. The punkah shown in Fig. 1 is 6 ft. wide, but widths up to 12 ft. can be driven by a single motor. The punkah is neat and compact, and is well worth the inspection of interested engineers, export agents, &c.

We also illustrate a new season E.M.I. fan in Fig. 2, and would remind our readers that Messrs. Hogan & Wardrop are now ready to supply to the requirements of the summer trade. They also hold stocks of ceiling, porthole and bracket fans suitable for operation in foreign climates. The firm's address is 2, Gresham Buildings, Basinghall-street, London, E.C.

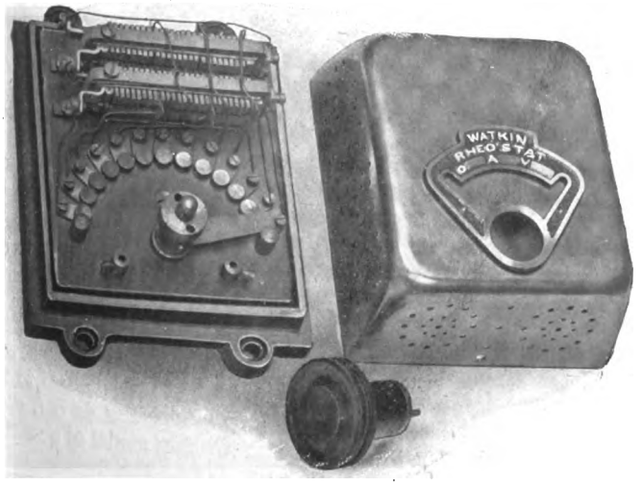
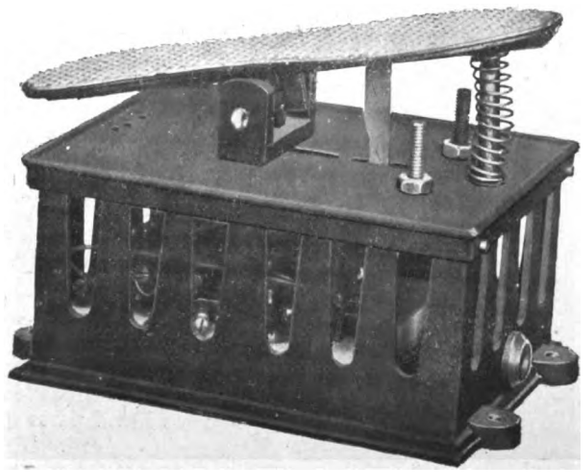
WATKIN MOTOR STARTERS.

The Watkin switch is well known in the electrical trade and amongst users of electric light as a convenient device for reducing the candle-power for incandescent lamps. The Adams Watkin Co. have taken steps to develop the switch for the control of small motors and also for regulating groups of incandescent lamps. The original type of switch has been followed closely in the motor starter pattern as far as the details of the resistance are concerned. The resistance elements are made up of a number of graphite blocks which are held on a suitable frame by clamping screws. Leads are brought out from this frame from points which subdivide the elements into groups each having a definite resistance value. These leads are connected to the stops of a multipoint switch over which a radial arm is arranged to sweep. The illustration will explain the details of this. A suitable cover is provided to enclose the moving contacts and through a hole in this cover the operating handle projects. The resistance is made up in a number of different sizes and for voltages from 50 to 250. The capacity ranges from 65 to 500 watts. A no-volt release can be supplied if required.



WATKIN MOTOR REGULATOR.



PEDAL REGULATOR.

We also illustrate the Watkin switch made up as a pedal switch and motor regulator. This is intended for small motors from $\frac{1}{8}$ to $\frac{1}{4}$ H.P. It should prove useful for the control of motor-driven sewing machines, dental engines, jewellers' lathes, polishing bobs, &c.

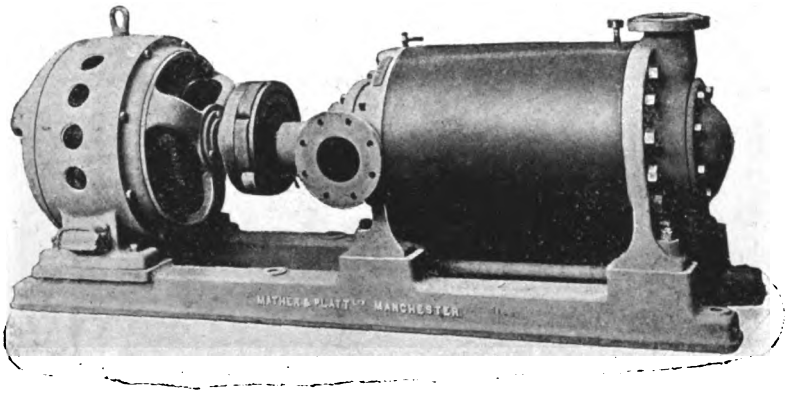
COLLIERY EXHIBITION IN MANCHESTER.

On Friday last the City Exhibition Hall, Deansgate, Manchester, was the scene of the opening of an important Colliery and General Mining Exhibition. Three years have elapsed since the mining industry of this country was represented at an exhibition, this having been held at Olympia, in July, 1908. The opening of the present exhibition in the Midlands should create a greater amount of interest than a show in the Metropolis, because Manchester is an industrial centre which is more closely in touch with the mining districts in all parts of the country, not excepting South Wales and Cornwall. The exhibits, though not large in the matter of numbers, are fully representative, and indicative in every way of the importance of mining interests in this country.



MATHER & PLATT MULTI-STAGE MINING PUMP.

In the unavoidable absence of Sir William Bailey, the exhibition was declared open by Sir T. Holland, who was introduced to the company by Mr. A. E. L. Chorlton, of Mather & Platt.

The exhibition has no particular display of electrical apparatus, but this may be regarded as a sign of progress rather than otherwise. Electric power is now taken for granted as an indispensable adjunct of mining operations, and it is no longer necessary for electrical manufacturers to urge the design of their products on the attention of mining engineers. On this account it seems in every way appropriate that electric motors and control gear should fill a natural and unobtrusive place in the machinery displayed at the exhibition.

Coming to the exhibits themselves, we may first refer to that of Mather & Platt on stand No. 79. In addition to the original Mather-Reynolds turbine pump, which is interesting as the first multi-stage pump ever constructed and which was designed for a 60 ft. head and a capacity of 800 gallons per minute, this firm shows its most recent types of high-lift turbine pumps. One of these has a capacity of 1,800 gallons per minute under 950 ft. head at 970 revs. per min., or 2,500 gallons per minute under 2,000 ft. head at 1,450 revs. per min. This pump is intended for direct driving by electric motor, and is of the seven-stage type, each stage forming a separate section, and the sections are bolted together to make up the complete pump. It is stated that this construction obviates the trouble of dismantling due to the rusting of the internal parts, such as is required when the working parts are placed in an outer casing. Each chamber is provided with separate feet, and the bedplate is extended to allow support to the end chamber while this is being withdrawn. Renewable bronze guide passages are fitted, and these are of substantial construction, being carried from the periphery of the propeller to the outside of the pump casing. A forced lubrication pedestal bearing is included, which is independent of the pump itself, being carried from the bedplate so as to give ample support to the shaft. This pedestal bearing is fitted at the driving end of the pump. At the opposite end the bearing is internal, and is cooled by the water passing through the pump. Grease lubricant is supplied to the bearing under pressure. A further interesting item in this exhibit is a high-lift turbine pump direct coupled to Mather & Platt's "Zoelly" steam turbine. This has an output of 1,500 gallons a minute and a 400 ft. head at 3,000 revs. per min. The turbine develops 200 B.H.P. with steam at 160 lb. pressure and a vacuum of 27 in. The pump is designed for high duty and high speed, and the impeller is of the double-suction type, with special passages equalising the pressure on each side. The pump is connected to the turbine through a semi-flexible coupling. In another portion of the stand may be seen a special form of vertical pump and motor, suitable for shaft sinking and unwatering.

A number of electrically-driven coal cutters are shown, and in this branch of the industry the exhibit of Messrs. Alfred Hopkinson is one of considerable extent and importance. It includes one three-phase longwall coal cutter, one direct-current machine of the same type and a number of parts, such as motor armatures, rotors and electrical accessories for use in connection with coal cutters. In this latter respect we may refer to specimens of cab tyre insulated cables, which have been recently developed for use in connection with portable electrical apparatus of all kinds in mines.

Messrs. A. Hirst & Son, of Dewsbury, also show a number of electrically-driven three-phase and direct-current disc coal cutters. The largest of these is fitted with a 3 ft. 6 in. cutter wheel of the loose box type. The controller and cable connections to the motor are carefully enclosed in steel piping. In fact, both motor and controller are totally encased. The same firm also exhibit a 24 in. shot hole drill for holes up to 2 in. diameter, 4 ft. 6 in. deep. This is electrically driven, and is shown in operation. A complete working model of a standard

REDUCED PRICES.

These are detailed in Pamphlet No. 213, just published, which will be sent post free on application.

The Sun ELECTRICAL COMPANY LTD.

118-120 Charing Cross Road, London, W.C.

coal cutter is among the other interesting exhibits on this stand. The Harland Engineering Co., who are the Lancashire agents for Messrs. Hirst, combine their exhibit with the above firm, and show a turbine pump direct coupled to a 500-volt direct-current motor, and a quantity of high-tension ironclad switchgear designed in accordance with the Home Office regulations.

A purely electrical exhibit is that of the Jandus Arc Lamp & Electric Co., who have a stand upon which they are showing their well-known regenerative lamp. This is particularly suitable for the illumination of pithead works, and should especially commend itself to mining engineers. It is a high efficiency flame lamp with a long life, 70 to 100 hours on one pair of carbons, and has the advantage of operating at a low cost—namely, 10 hours for 1d. The candle-power is 4,000 maximum at 15 degrees from the horizontal, and the makers claim that it will replace four to eight ordinary type arc lamps, giving a better light for less cost. Mining engineers visiting the exhibition should take an opportunity of inspecting this exhibit.

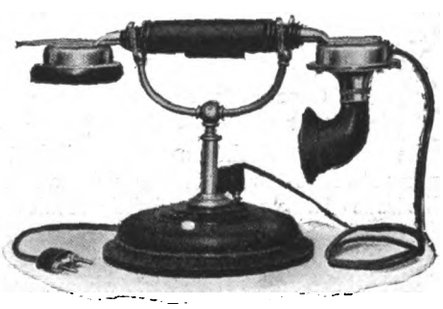
The British Westinghouse Co., who have fitted up the Engineers' Club with "Auriga" metal lamps, have appropriately decorated the club with a number of large framed photographs of electrical plant and machinery which they have installed in mines and collieries. These installations include turbines, generators, motors and switchgear, and the pictures are both instructive and of more than ordinary interest. They indicate the rapid strides made in the applications of electricity to mining operations.

An exhibition which is not without interest is that of the Great Central Railway, who show a massive cabinet in which views of G.C. locomotives and steamers are mounted. These are illuminated at night. High up on the wall of the Exhibition and facing the main cross aisle is a wash drawing of Immingham Dock, which is in process of construction, and is being equipped with the most modern dock and harbour plant. This view has been prepared by the Great Central Railway, and shows the extensive character of the undertaking. We may remind our readers that the company are offering special facilities for reaching the Exhibition in Manchester both from London and the Midlands.

The Exhibition has been organised by the "Engineering Review," and during the past two days the annual meeting of the National Association of Colliery Managers, under the presidency of Mr. G. H. Winstanley, has been held in connection with the Exhibition.

"WESTOPHONES."

There should now be a brisk demand for domestic telephones, judging by the literature which the various telephone manufacturers are distributing on the subject. The Western Electric Co. send us particulars of their private telephone instruments, to which they have given the trade name "Westophone." These instruments are intended for connection to existing bell circuits and can be supplied as wall or table sets. An illustration of the latter is given herewith. The instruments are extremely reasonable in price, and the makers state that they are "not a toy but a well-constructed telephone, built to last." They are finished in ebonised wood with nickel-plated fittings.



WESTOPHONE TABLE SET.

The Western Electric Co. also send us particulars of their interphones for commercial and industrial use. We have referred to the general excellence of these instruments on a previous occasion.

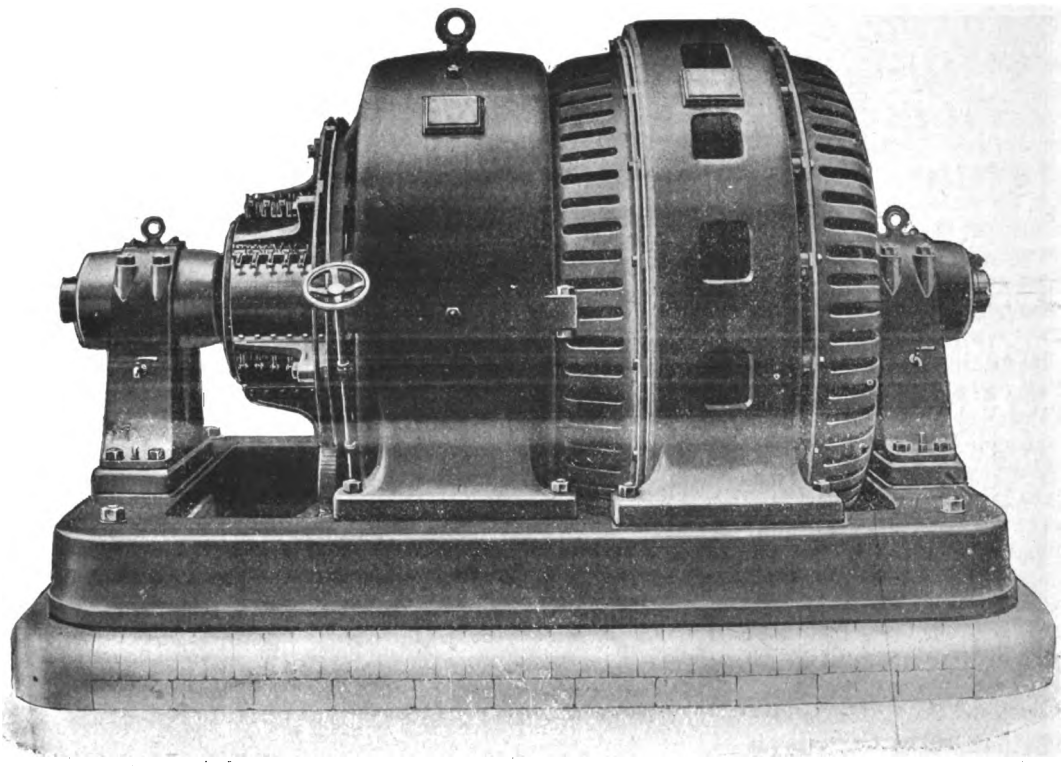
PEEBLES MOTOR CONVERTERS.

The controversy which raged some years ago around the question of the respective merits of motor generators, rotary converters and motor converters has now practically subsided, and each class of machine has filled its own particular niche in electrical working. The motor converter practically revived interest in the controversy by placing an entirely different aspect upon it. The machine possessed such a variety of novel features that it appealed largely to station engineers who were engaged in the extension of their supply for industrial power purposes among the type of consumer requiring a direct-current supply. The issue of a new edition of their Peebles motor converter list by Bruce Peebles & Co. recalls the above-mentioned controversy, and it also gives striking evidence of the utility of these machines and the variety of uses to which they have been put.



General View of Two-bearing Peebles Motor Converter.

We may recall the most notable features of the motor converter as a matter of interest. In the first place it dispenses with transformers, the line voltage being brought directly into the alternating-current side of the unit. This naturally reduces the size of the sub-station for machines of this class. It also simplifies the switchgear and practically solves the problem of the skilled attendant. In the construction of the machine only two bearings are required for units of comparatively large output, and it is only in the large capacity machines that three bearings are introduced. A further interesting feature of the machine is that all rotating parts are operated at low voltage. In principle the unit comprises an ordinary induction motor and a rotary converter mechanically coupled on the same shaft; the rotor winding and the armature winding of the induction motor and rotary respectively are connected in parallel. The number of poles of the alternating-current machine is such that the frequency of the currents introduced in the armature winding is the same as the frequency of the rotor currents. These two windings can be connected together when the E.M.F.s are equal and in phase, and after this has been done the speed remains constant, and the two machines connected in tandem function as a single synchronous machine. Half the electrical energy supplied to the induction motor is converted into mechanical energy, transmitted by the shaft to the direct-current portion of the converter; the other half of the energy is transferred to the rotor winding and thence to the converter armature. The converter runs at a speed equal to half the primary frequency, so that it can be made of smaller proportions than the ordinary direct-current generator for the same output and frequency.

The machines are built up in sizes suitable for the supply of traction loads, in which case they are arranged to compound automatically from 500 volts at no-load to 550 volts at full-load. They are capable of withstanding 100 per cent. overload without sparking, and are free from liability to reversal of polarity either when starting up or when "shorts" come on the line. The lighting motor converters are made shunt or compound wound according to requirements, and the standard shunt machine will operate on a 5 per cent. voltage drop from no-load to full-load with practically unity power factor. Special motor converters are also made for both traction and lighting and for operation from direct-current circuits for the supply of alternating-current energy at high voltage.

In the publication to which we have referred a comparison is given between the motor converter, the rotary converter and the motor generator, which places the advantages of the first named well to the front. We give an illustration of a standard two-bearing type converter above. Interested engineers should apply for pamphlet No. 20B to the offices of the company, East Pilton Works, Edinburgh.

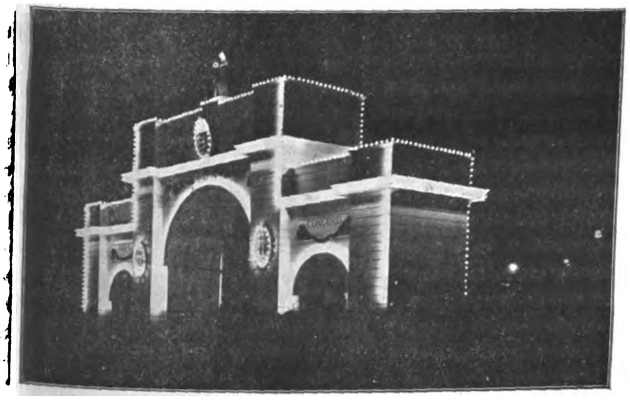
ILLUMINATION EFFECTS.

Carbon filament lamps will no doubt be almost generally used during the forthcoming Coronation celebrations, because the temporary nature of the various installations will prohibit the higher priced metal lamps being widely adopted. Siemens Bros.' Dynamo Works inform us that they are now holding large stocks of carbon lamps which can be supplied immediately at remarkably low prices, which will, however, only



Arch Illuminated with Siemens Carbon Lamps.

hold good until the present stocks are exhausted. Orders will be executed in strict rotation, and it would be advisable to send orders or reserve sufficient quantities immediately. These lamps have been in great demand for illumination work, and we illustrate here some night effects which were obtained during the Royal visit to South Africa on the occasion of the opening of the Imperial Parliament there. The many thousands of lamps employed in these decorations were supplied by the Siemens South African branch, and, as will be seen, highly satisfactory results were obtained. Similar lamps will be used in the various schemes which the firm are catering for, and the actual fixing and erecting work will be placed in the hands of competent electrical contractors. Copies of the company's Coronation devices and accessories' list will be sent on request to any who are interested in illumination schemes.

SIEMENS ENAMELLED WIRES.

The enamelled wire is the result of considerable manufacturing experience, and Siemens Bros. & Co. are now publishing particulars of this class of conductor. The enamel is hard, flexible, watertight and capable of withstanding high temperatures for short periods without injury. It is practically non-inflammable and capable of resisting the action of most of the re-agents met with in general practice. Its dielectric strength is high, and it can be made to withstand high electrical pressures if required. We understand that there is no electrolytic action under the most unfavourable conditions. The applications of enamelled wires are, of course, wide and varied. In the saving of space alone they have an advantage over silk or cotton-covered wires for the purposes for which these are now adopted ; further, they are suitable for many purposes where such wires cannot be employed at all. They are specially recommended

ELECTRIC COOKING AT GRIMSBY.

The advantages of electric cooking are best demonstrated in the summer months when gas is at a premium and coal fires are anathema. Mr. W. A. Vignoles, electrical engineer at Grimsby, is keenly alive to the possibilities of increased business from this direction. He has been holding an exhibition at which the merits of electric cooking with an E.O.A. Eclipse oven were successfully demonstrated by Miss G. A. Paget. Lectures were given in connection with the demonstrations. We understand that upwards of 1,000 persons attended during the course of the week. Great interest was taken in the show, and a few orders were booked, in addition to a large number of inquiries being received. Suitable literature was distributed to each visitor, and among the pamphlets was a most convincing testimonial from a Grimsby lady resident, who is the proud hostess of an electric household. During a period of 10 weeks the cost worked out at 3s. 4d. a week for cooking and heating; this includes the preparation of three meals daily, and the heating of all water required. The demonstration was arranged in co-operation with the Electric & Ordnance Accessories Co., whose Eclipse apparatus was used throughout. We described this apparatus in our issue of December 2, 1910. We extend our congratulations to Mr. Vignoles on his enterprise.

WESTINGHOUSE TURBINE PLANTS.

It is a regular practice in the industry for electrical manufacturers to sub-contract to engine and turbine builders or vice versa, when the equipment of generating plants, &c., is under consideration. The British Westinghouse Co. now intimate that they are in a position to supply the complete generating plant from "stop valve to switchboard," so to speak, and that such plant, in the shape of steam turbines, turbo-generators, turbo-blowers, turbo-pumps, condensers, &c., is made complete in their large works, Trafford Park, Manchester. They point out that there are certain advantages to be derived from the placing of the whole of a contract with a single firm. The responsibility is undivided, the question of delivery is less troublesome to deal with, the plant is the product of a single organisation having but one "body to be kicked, &c.," and grievances or complaints are confined to the smallest possible area. It is urged that these are sufficiently good reasons for the placing of business with the firm in question. In so far as power installations are concerned, the arrangement should work to the mutual advantage of the parties concerned because guarantees of coal and steam consumption can be undertaken with a greater degree of certainty than is probably possible where plant is sub-contracted for.

THE ELECTRICIAN COMMERCIAL AND INDUSTRIAL SUPPLEMENT.

C. & I. Supplement No. 86.] MAY 26, 1911. [Gratis to Subscribers.

MANCHESTER COLLIERY AND MINING EXHIBITION.

CONCLUDING NOTICE.

We understand that this exhibition, which closes to-morrow, May 27th, has been a distinct success from the commercial point of view. After all, an exhibition of this kind does not provide any particular attractions for the general public. The fact that the annual convention of the National Association of Colliery Managers coincided with the opening of the exhibition ensured the attendance of large numbers of interested engineers and gave an excellent opportunity to the exhibitors of bringing their products to the notice of interested prospective buyers.

One of the most prominent exhibits was that of Tilghman's Patent Sandblast Co., who exhibited a two-crank air compressor of the vertical high-speed two-stage type. This has a capacity of 400 cubic ft. of free air per minute delivery against a pressure of 100 lb. per sq. in. This is fitted with a patent automatic multiple plate system of valves, and forced lubrication is supplied to all bearings and slides. The compressor was shown in operation direct connected to a 75 B.H.P. Lancashire Dynamo motor, connection being made through a flexible coupling. The iron door of the crank chamber was replaced by one of plate glass, and through this the cranks could be seen at work and the splash system of lubrication for the big ends. The compressor is fitted with an automatic unloader on the air inlet, and this is operated by air pressure in the receiver. All dust in the air is extracted by an improved air washer before it enters the compressor cylinders. Running silently with its motor this compressor constituted one of the most attractive items in the exhibition.

The Lea Recorder Co. made a good show of their well-known V-notch recorders for the measurement of the flow of water and also of certain acids. The exhibit comprised one Lea patent self-contained recorder with 5 in. chart, flow chamber and notch tank, also one self-contained set with 6 in. recorder V notch having a capacity of 50,000 lb. of water per hour. This was shown in operation measuring steam consumption. The most recent pattern of combined indicating, recording and counting instrument was also exhibited in operation. This apparatus demonstrates the method employed for measuring water when the instrument is placed at a distance from the notch tank. The Lea Recorder Co. have also developed a midget portable testing apparatus which is suitable for dealing with small flows. This formed one of the attractions of the exhibit. The stand was completed by a number of photographs depicting actual installations of the Lea recorder in central electricity stations and power plants in practically all parts of the world. The mining engineer is perhaps not yet educated up to the importance of measuring his steam consumption, principally because coal is cheap at the pit bank, at the same time the modern turbo-electric installation, in which the power plant is concentrated rather than scattered, has impressed upon the colliery engineer the absolute necessity for the running of the plant upon highly economical lines. With the Lea apparatus it is possible to do this with the minimum of outlay and also with practically no skilled attention. This latter item is of considerable importance, because, as a rule, the number of skilled engineers in a colliery is small.

Messrs. Matthews & Yates, who are well known as ventilating engineers, had an impressive exhibit with their "Cyclone" blowers and exhausters, designed specially for colliery ventilation, induced draught for boilers, and all kinds of difficult ventilation problems. These fans were shown in operation, both direct connected and belt driven from electric motors. The Cyclone refuse and dust-collecting and separating

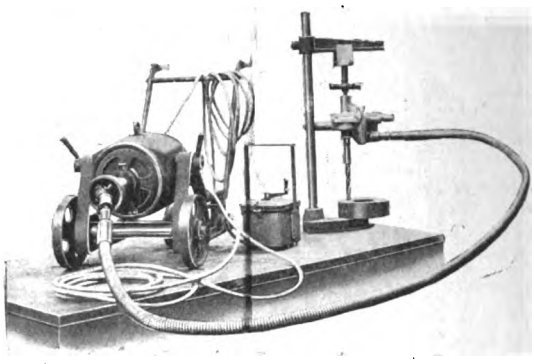
CARDIFF	NEWCASTLE	CAPE TOWN	MADRAS	RANGOON	TORONTO

plant for the collection of coal-dust from screens and tipplers, also from wood-working mills and carpenters' shops, was among the features of the exhibit. In addition, a show was made of Cyclone autogenous welding and cutting plant for the welding and cutting of all kinds of metals from thin sheets to pieces 6 in. or 8 in. thick.

An exhibit which is not without interest is that of the Power Gas Corpn., Stockton-on-Tees. This company owns the patents and manufactures Mond producer gas plants from 100 to 30,000 H.P. and Mond gas plants with ammonia recovery, also producer gas plants from 10 H.P. upwards for every class of fuel. The exhibit comprised a large Mond gas and sulphate of ammonia recovery plant, and also a large number of photographs of gas plants actually installed. While it will be difficult to prophesy that power supply to collieries will in future be given from large plants operated by gas engines, it is at the same time of interest to note that engineers are working persistently at the problem of the supply of cheap gas for the operation of large engines, and the work of the Power Gas Corpn. in this respect is worthy of note.

PORTABLE ELECTRIC DRILLS.

The average modern workshop is now fitted with electric power circuits and in addition to the operation of the main shaft and the principal tools by electric motors there is generally a demand, particularly in engineering workshops, for portable tools. We illustrate a modern pattern of Witton-Kramer drilling outfit with trunnion type motor. This can be supplied for use on direct-current and alternating-current circuits, and holes from ½ in. to 1½ in. can be drilled with the various sizes of outfits. The equipment includes motor mounted on trunnion trolley, flexible length of armoured conductor and modern pattern of flexible shaft with steel wire core. The trolley head has a gear reduction of 1 in 4, and is fitted with a suitable clutch. The outfit is light and portable and can be used for drilling holes in practically any required position. A new list (K 20), issued by the Witton-Kramer



WITTON-KRAMER PORTABLE DRILL OUTFIT.

Electric Tool & Hoist Co., Witton, Birmingham, contains full details of these machines, together with a variety of other portable tools, such as polishers, blowers, boiler cleaning outfits, &c.

SILVERTOWN GALVANIC BATTERIES.

A very complete list of Leclanché and other batteries is being sent out by the India Rubber Co., Silvertown. Practically every known type of primary battery is listed and priced. We illustrate a set of Silvertown Leclanché firing batteries of 10 cells, complete in polished teak case. The cells are of the

SILVERTOWN LECLANCHÉ CELLS IN CASE.

six-block agglomerate type made up in a wood case. This construction is lighter and more portable than a stoneware cell. The top is sealed in so that there is no loss of liquid either through evaporation or spilling. We understand that these cells are largely employed by the Government for torpedo firing and also for mining blasting operations. A line of Silvertown-Leclanché medical batteries is listed, and these are supplied in sets of 20 to 60 cells. Considerable space is devoted to the Silvertown Bleecklove primary battery, which has an E.M.F. of 2·7 volts and which we described some time ago when it was first brought out.

B.T.H. CORONATION DEVICES.

We have received particulars of a wide range of Coronation devices which the British Thomson-Houston Co. are offering for the forthcoming celebrations. The list describes complete emblematic devices with the portrait of the King or monograms of the King and Queen, crowns, scrip and block letters, illumination strip, multi-coloured lanterns, festoon strip, &c. B.T.H. carbon lamps and "Mazda" metal lamps are also included in the list. The latter are for 25 volts and have a 6-watt consumption. They are intended for use on alternating current circuits where transformers are employed for reducing the service voltage. We illustrate one of the emblematic devices herewith. In conjunction with the Coronation list a full list of the surplus stock of carbon lamps is offered at prices ranging from 2s. to 18s. per dozen. Contractors should make earliest application for this list, as doubtless there will be a big demand for lamps of this class.

B.T.H. Emblematic Coronation Design.

AN ALL-CHINA SIGN HOLDER.

The Benjamin Electric, Limited, have introduced a new design of lamp-holder, illustrated herewith, which possesses sundry novel features. This holder is useful for outlining borders and sign-letters, and is adapted for mounting on the back of the sign with the barrel projecting through the wood surface. This brings the lamp close to the surface to be illuminated, giving a better lighting effect. The holder is weatherproof, there being an original method of preventing moisture entering the lamp-holder after the lamp has been inserted. The connecting-up is quite simple as the terminal screws lie in the grooves at the back of the base. The holder is recommended

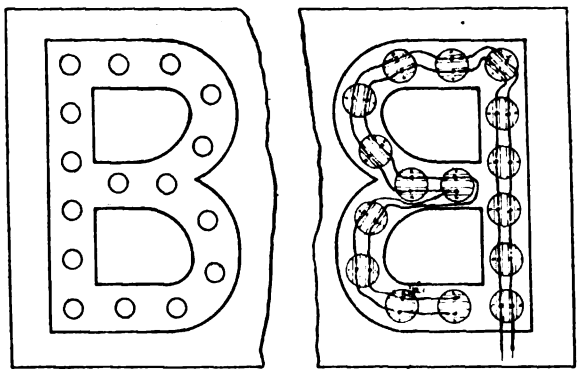
for permanent work as well as temporary installations such as for the Coronation. It is an improvement on the ordinary



BENJAMIN CHINA HOLDERS MADE UP FOR OUTLINING LETTERS.

brass batten holders which are not weatherproof and also deteriorate rapidly when exposed to the elements.

REMARKABLE RUBBER BALLS.

One of the most interesting exhibits which will be seen at the International Rubber and Allied Trades Exhibition at the Royal Agricultural Hall in June and July comes from Brazil. It consists of 500 balls of rubber, which will be piled up in a pyramid occupying a space of about 29 ft. 2 in. by 21 ft., and will reach approximately a height of 20 ft. The average weight of each of these balls is 56 lb., and at 6s. per lb. would work out at £16. 16s. per ball, and the whole would cost £8,400. In addition, Brazil will show a ball of rubber weighing about a ton. This will be cut open at the beginning of the Exhibition, and prizes will be given to those who estimate the correct weight at the conclusion of the Exhibition. This is the largest ball of rubber that has ever been seen in this country.

PUBLICITY COMMITTEE PAMPHLETS.

A fresh set of circulars has been issued by the Electric Supply Publicity Committee and covers literature for distribution to both consumers and non-consumers. One of the most interesting of the pamphlets is one entitled "Electricity in the Nursery." The main intent of this is for non-consumers, urging primarily the adoption of electric light. The nursery is, of course, merely taken as a typical instance as illustrating the great convenience of electric light. The circular also deals with various other electrical apparatus which should prove useful in the nursery.

The issue includes a feature which will appeal to every undertaking, and this is a booklet on electrical apparatus which has been prepared with a view to familiarising existing consumers with the various types which can be used on the supply mains. It is also useful for distribution to non-consumers. The apparatus dealt with in the present booklet includes fans, grillers, kettles, irons, vacuum cleaners, &c. This particular booklet can be enclosed with the ordinary correspondence, receipts, &c.

The following circulars are also included in the issue:— An illustrated circular for non-consumers addressed to housewives, urging the value of electric light for lessening the work in the home. Two cards, with illustrated designs on one side, advertising respectively power and lighting, the other sides being left blank for use as postcards, or for giving particulars of rates, &c. Two cards, advertising electric light, in the form of reply postcards, suitable for being enclosed with other circulars. A card advertising electric lamps and urging that the best lamps should be adopted, suitable for use of undertakings who give advice, &c., on lamps. Illustrated circular to property owners, builders, landlords, &c., pointing out that houses should be wired prior to tenancy, on the grounds that the letting and selling is easier and also that there is a save in re-decoration. Circular on the safety of electric light, giving important testimony on the part of insurance companies. Power leaflets addressed severally to engineers, bakers, printers; also dealing with electro-plating works and saw mills. These leaflets have been carefully compiled and will be of use for sending out to the various trades or for following up inquiries, as each trade has been dealt with from its own particular point of view.

PUBLIC TIME SERVICE.

A public clock was set going at the Marble Arch on the 23rd inst. and was presented to the Borough of St. Marylebone by Mrs. Mocatta, of Great Cumberland Place. It consists of two large dials facing East and West, fixed upon an arc-lamp standard in Oxford-street, opposite the end of Park-lane. The dials are operated by an electrical time transmitter contained in a cast-iron pillar on the refuge. The instrument receives an electrical impulse every hour from Greenwich Observatory and transforms it into the half-minute impulses necessary to propel the hands of any number of clock faces. It does this quite automatically, so the clock never requires to be wound up. Though clock faces have as yet only been fixed to one arc-lamp standard there is no reason why a pair should not be mounted on every other lamp post down the street as the controlling mechanism will operate any number and the dials themselves are quite simple, the only works they contain being one wheel and an electromagnet. The work has been carried out by the Synchronome Company on the system invented by Mr. Hope-Jones, who has been advocating municipal time service for many years. He looks upon this as an important step in the right direction and an object-lesson to other boroughs, both metropolitan and provincial.

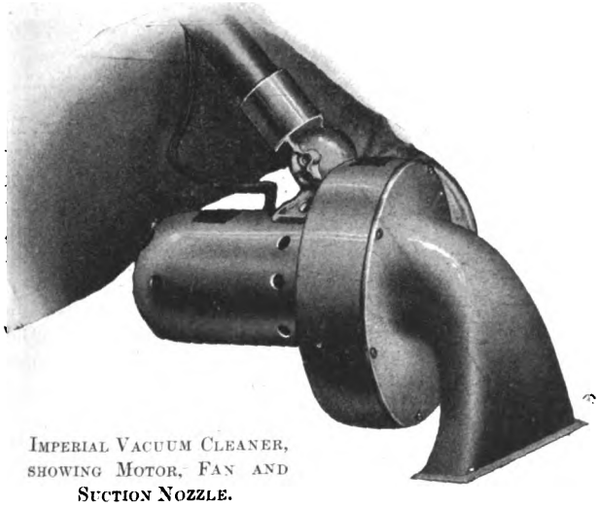
THE IMPERIAL SUCTION CLEANER.

We have been given an opportunity of inspecting a new type of suction cleaner which is intended specially for domestic service. It is of what we may call the electric broom type, in that the motor, suction fan and nozzle are made up as a complete unit and attached to a long handle which is used to pass the nozzle over the floor surface to be cleaned. It will be seen from the illustration that the motor is in a horizontal position and that the fan is directly attached to it. It is stated that the speed of the motor and fan is 10,000 revs. per min. Fan and motor are enclosed in an aluminium casing, which is splayed out directly below the fan to form the suction nozzle. The placing of the fan in a horizontal plane ensures a direct suction at the nozzle itself. The delivery nozzle also forms part of the



IMPERIAL VACUUM CLEANER, SHOWING MOTOR, FAN AND SUCTION NOZZLE.

aluminium casing and to this outlet the dust collecting bag is attached. The bag hangs immediately below the operating handle, where it is quite out of the way. By the use of a horizontal motor it is also possible to run the cleaner underneath beds and furniture without damaging the motor or the casing.

The Imperial suction cleaner can be used for curtains and other furniture by the attachment of a flexible hose and suitable nozzles to the intake on the fan casing. The suction at the end of the nozzle is almost as powerful as that obtained without it. The various attachments for use with the flexible hose will allow of the cleaning of walls, cornices, skirtings, radiators, book cases, &c. The cleaner can be fitted with wheels if required, and we understand that it has been in successful operation in bioscope theatres, where there is naturally a large amount of dust to be cleared away each day. In this case the flexible hose is employed not only for cleaning the chairs, but also for the ornamental plaster with which these places of amusement are generally embellished. The cleaner has also been tested on carriage cushions, and found to extract dust even though the surface is very irregular.

THE C.M.B. BALANCER KIOSK.

When Messrs. Crompton introduced the C.M.B. converter some two years ago we published a detailed description of the principle and construction of the machine. As we remarked in a recent issue, we had an opportunity of looking through the machine shop at the Arc Works, Chelmsford, and noticed a large number of these machines in process of manufacture. This may be taken as indicative of the continued demand for this interesting type of machine.

A new edition of the C.M.B. converter pamphlet has just been issued, and while this describes the functions and applications of the converter it also includes an interesting example of its utility as a three-wire balancer. The machine is so compact that it can be placed inside a cast-iron pillar and installed, together with the necessary switchgear, at ground level on a direct-current network The adjoining illustration depicts the balancer and its gear inside a cast-iron kiosk. In this form it can be placed at the far end of a long feeder, and be entrusted with the balancing of the network in some small outlying district. The kiosk need not be erected on the side walk of a main road, it can be placed in any out-of-the-way street at a point most convenient for the balancing up of the system. The cost of sub-station buildings is saved, together with that of extensive switchgear and connections.

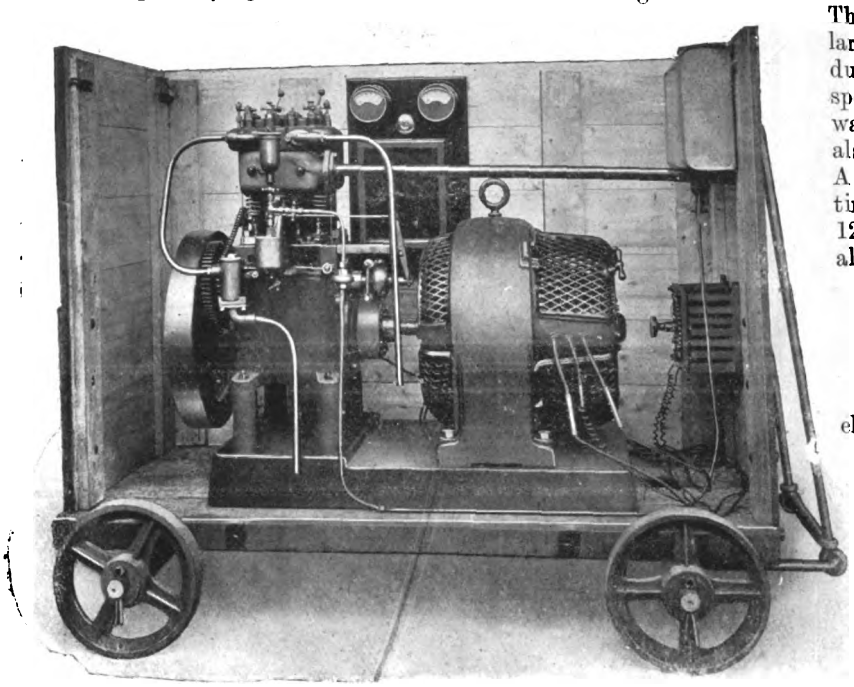
"KELVIN" LIGHTING SETS.

The number of small isolated electric lighting and power sets is being constantly added to, a fact which indicates that there is business in these tiny units if contractors will only go after it. The latest arrival is the "Kelvin," which, as its name implies, hails from Glasgow. Details of this petrol-paraffin unit have just been sent to us by Messrs. Fyfe, Wilson & Co., Bath-street, Glasgow. We illustrate a portable outfit of 3 kw. capacity, mounted on a substantial and wheeled truck for transport purposes. The engine is a two-cylinder machine, 3½ in. by 4¾ in., and is fitted with l.t. magneto throttle



KELVIN PORTABLE LIGHTING SET.

governor, vaporiser, water-circulating pump, &c. The galvanised fuel tank holds fuel and oil for a 12-hour continuous run. The sets are listed in sizes to supply from 50 to 300 lights. By fitting ball bearings to the engine the overall length has been considerably reduced. In the 16 kw. size a four-cylinder engine is employed and this is provided with a safety starting device. Interested contractors and shippers should apply for the catalogue describing these plants in full.

HAIR DRYERS.

By a combination of an enclosed electric fan and resistance element it is possible to make up an effective form of dryer which can be used principally for drying the hair and also as a hot and cold air douche. A device of this pattern is being put on the market by the Electrical Co., and is supplied for direct-current and alternating-current circuits of any lighting voltage. The fan is completely enclosed and the air is taken in through a number of holes at the side of the casing and discharged through a nozzle which is surrounded by a wire resistance which is heated by the passage of the current passing through the fan. A pleasing effect is produced by the application of the warm air to the bare skin. The air blast is sufficiently strong to carry away moisture rapidly from the hair or from other surfaces which require drying. The apparatus is moderate in price and the Electrical Co. will be pleased to furnish full details.

VULCANISED FIBRE.

Our readers will be interested to note that Messrs. Mosses & Mitchell have again enlarged their turning and cutting shops in order to cope with the increased demand for their products. This extension of the works has proceeded side by side with a large increase in the number of the staff. The principal products of the company are vulcanised fibre and electric specialities, these being supplied as sheets, tubes, rods, washers, rings, cones, &c. Gear and spur wheels in fibre can also be supplied, also brake shoes, bushes, switch bases, &c. A speciality is also made of condenser ferrules and insulating saddles and staples. The works of the company are at 122-124, Golden lane, London, E.C., and we understand that all interested enquiries will receive prompt attention.

"ECLIPSE" ELECTRIC COOKING.

In our last issue we commented upon the demonstration of electric cooking apparatus made by the Grimsby Corporation. We understand that this demonstration was mainly due to the enterprise and co-operation of the Electric & Ordnance Accessories Co. This company is carrying out a publicity scheme which includes, in addition to the distribution of a quantity of literature on the subject of "Eclipse" cookers, also a number of demonstrations in important centres of the actual apparatus. This cannot fail to impress upon the people, and particularly those who are already electricity consumers, the advantages and general importance of electric cooking. The summer months are eminently

suitable for demonstrations of this character, and it is to be hoped that the enterprise of the manufacturers will meet with the success which it deserves.

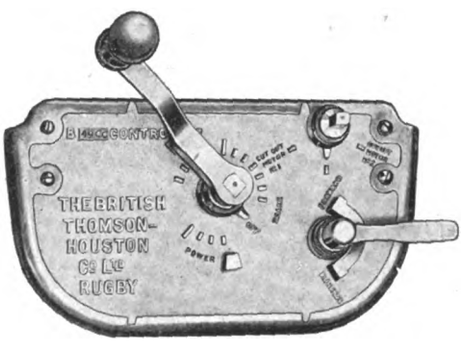
We give an illustration of the "Eclipse" oven as shown and demonstrated during the Grimsby Exhibition.

A NEW TRAMWAY CONTROLLER.

Tramcar controllers of the braking type now in general use are arranged so that if the car is running forwards, on moving the handle to the brake notches currents are generated in the motors producing a retarding torque, the direction of these currents being such as to strengthen the magnetism of the fields. If the car is running backwards and the controller handle is moved to the brake notches the currents generated in the motors will demagnetise the fields, so that no braking effect is produced.

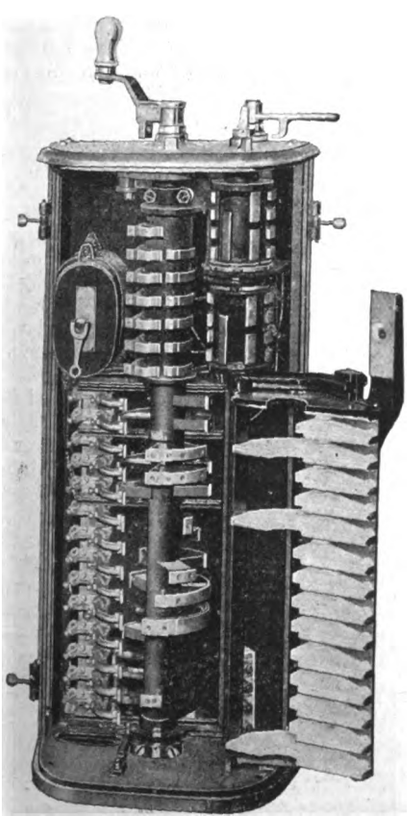
To obtain a braking action when the car is running backwards, the British Thomson-Houston Co. have designed and manufactured controllers in which, when the controller handle is moved to the "off" position, connections are made which cause one or more of the motors to act as generators, producing a braking effect. These connections give no braking action during forward running if the handle is in the "off" position. A preferable arrangement is one in which the motion of the control handle, which produces braking for forward running, will also produce braking for backward running. The B 49 B.T.H. controller shown in the illustration will give this result. The reverse switch handle may be in either the forward or reverse position, when, by moving the main control handle to the braking notches, a rheostatic braking effect will be obtained for either forward or backward motion in the car.

This controller is suitable for use with two 40 H.P. 500 to 600-volt series motors, and has four series, four parallel, and seven brake-controlling points.

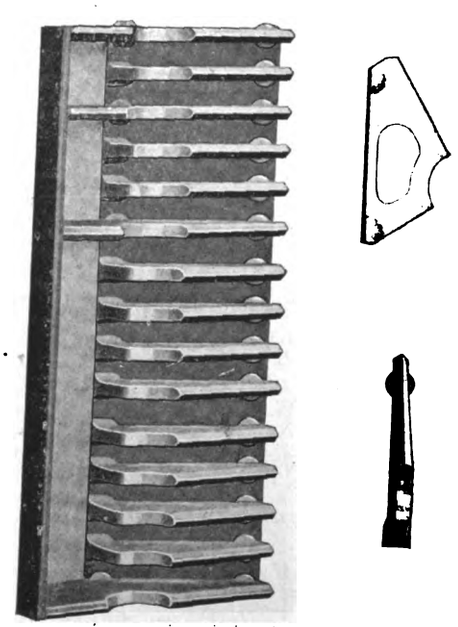


CAP PLATE OF NEW CONTROLLER.

Another important feature of the B 49 Controller is a mechanism for cutting out a defective motor without removing the cover of the controller. To cut out a motor it is only necessary to remove the reverse switch handle from its spindle and apply it to the cut-out spindle which projects through the cap plate, shown in the illustration, near the back edge. This cut-out spindle has three running positions, a central position for which both motors are in circuit, and a position on each side to cut out either motor. An interlocking device prevents the reverse switch being moved unless the cut-out switch

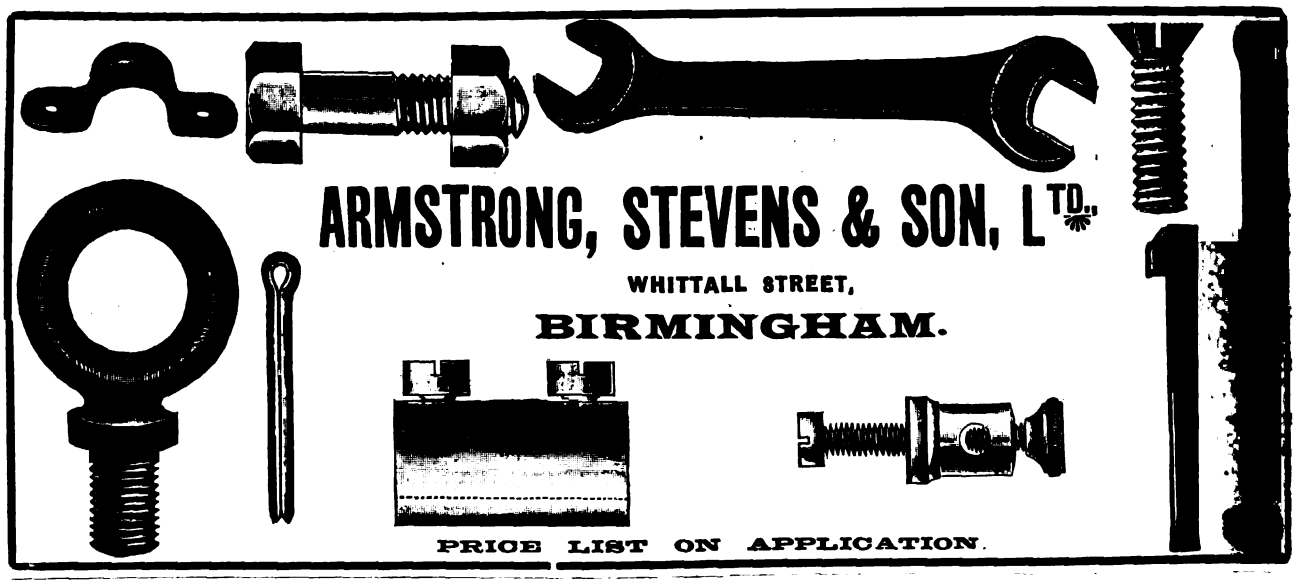


GENERAL VIEW OF NEW B.T.H. TRAMCAR CONTROLLER (OPEN).



ARC DEFLECTOR OF NEW CONTROLLER.

Digitized by Google



spindle is in one of its three running positions. The usual interlocking mechanism is provided to prevent the reverse switch being moved unless the main drum is in the "off" position.

The arc deflector of the controller consists of fire-proof barriers of strong mechanical construction, the large deflector plates being supported at both ends, and the small plates moulded with large bosses for the fixing screws, thus providing rigid fixing for the plates.

A powerful magnetic blow-out is provided for all fingers of the main cylinder on which arcing takes place, and an insulating trough surrounds the back half of the main cylinder protecting the frame from the influence of the arc or live parts. The trough is divided into sections by barriers; these, with the arc deflector which covers the front half of the main cylinder, form separate chambers for enclosing the various sections of the cylinder which may be at different potentials.

The brake cylinder is mounted on the main cylinder spindle in accordance with standard B.T.H. practice, this preventing any possibility of change in the relative positions of brake cylinder and handle which may occur, due to wear on the gears or cams when the brake cylinder is mounted on a separate spindle.

Ample space for the incoming cables is provided, and the arrangement of the various parts enables the wiring to be easily and quickly effected.

ELECTRIC CHARGING MACHINES.

We learn that Messrs. Babcock & Wilcox, Ltd., now include among their manufactures steel works cranes and charging machinery, and have just received an order for a slab-handling and charging machine, of 5-ton capacity, from James Dunlop & Co., Calderbank Steel Works, Scotland. The machine is electrically driven in all its motions and is designed, with several important improvements, to secure rapid handling of the slabs. It is expected that this machine will increase the output of the rolling mills and reduce the present labour costs at Calderbank.

NEW TRADE LITERATURE.

During the past week we have received a big budget of literature from various electrical manufacturers. We refer more fully to a number of special pieces of apparatus which figure in these lists in the pages of the "Supplement" this week.

FREEZOR FANS.—Section E of the General Electric Co.'s main catalogue describes and prices Freezor electric fans. The first item that meets the eye in the list is a table of reduced prices for the coming season. The list itself is replete with information on the subject of Freezor fans of every type. A noticeable improvement this year is the introduction of "airo blade." In this three narrow blades are placed one behind the other in the same plane on the fan motor-shaft. The blades are of the two-way type, and it is stated that for the same energy consumption 30 to 40 per cent. more air is moved. The pitch of the blade is determined by the speed of the motor, and in making inquiries for this type of fan the speed should be specified. The company is prepared to quote for the fitting of these blades to existing fans.

WATER LEVEL APPARATUS.—Siemens Bros. & Co. send us a copy of catalogue No. 533, in which their water-level transmitters and indicators are fully described. Various applications of this interesting and useful device are given, together with a number of illustrations.

WITTON SWITCHBOARDS.—Section X of the G.E.C. catalogue is devoted to descriptions, diagrams, illustrations and prices of Witton switchboards. Considerable care has been exercised in the preparation of this list, and the diagrams are noteworthy for their clearness and the interesting problems with which they deal. In addition to complete switchboards there is a useful list of accessories in the shape of switch material for building up various classes of gear.

WESTINGHOUSE FANS.—A pamphlet is being issued by the British Westinghouse Co. in the shape of supply list No. 140.2. In this the company's "Ariel" fans for desk, bracket, ceiling and cabin use are described and priced in detail. This list will be ready in a fortnight.

KINEMATOGRAPH RESISTANCES.—The M. & C. Mfg. Co., Conduit place, Paddington, London, W., have issued a useful list dealing with their regulating and plain resistances. These are built up in sizes varying from 5 to 100 amperes capacity, and are specially recommended for use in regulating arc lamps for kinematograph lanterns. The resistances are of the coiled wire type, and are arranged on suitable insulators fixed in metal frames.

FOSTER TRANSFORMERS.—A leaflet from the Foster Engineering Co. illustrates a 35 kw. and a 50 kw. Foster transformer. The company state that they make a special feature of large transformers for step-up or down single or polyphase, stationary or portable service.

C. & I. Supplement No. 87.] JUNE 2, 1911. [Gratis to Subscribers.

"SUN" SCREWED TUBE SYSTEM.

The many installations which have been carried out on the "Kalkos" system of wiring will have familiarised electrical contractors with the general merits of this method. When "Kalkos" was first brought out some four years ago the boxes for switches, ceiling roses, junctions, &c., were of brass, and the tubes were sweated into them. The type of box employed possessed a number of novel features, amongst which the adjustment ring was the most striking. With this fitment it is possible to utilise the same box for surface or flush wiring simply by the alteration of the position of the adjustment ring. To all intents and purposes this ring forms a false bottom to the box, on which the porcelain of the ceiling rose or switch is made to rest.

The general scheme of the "Kalkos" box has now been worked into the "Sun" screwed system of wiring. The boxes are of iron, and can be supplied with back entry or with side entries from one to four in number. The illustration shows a one-way "Kalkos" iron box into which a surface switch has been fitted. This view will serve to show the general arrangement of the other patterns of boxes. The lid of the box is another adjustable feature, and it can be supplied in two depths for surface or flush wiring.

By the use of the "Kalkos" switch (which we described in a recent issue) in these boxes a water and air-tight switch box is obtainable. When the switch is placed in position on the adjustment ring and held securely by the cover, the switch dolly is automatically earthed. This affords complete immunity from shock, because it is impossible for the dolly to become charged while the system is efficiently earthed. This automatic earthing is of great advantage, because no special connections have to be made, the act of screwing up the cover making the only contact necessary.

Similarly, with the "Kalkos" three-pin plug, which has been introduced to comply with the regulations which require the earthing of portable lamp-holders. The earth terminal in the plug socket is connected to a brass tongue, which projects below the porcelain base of the socket, and makes a rubbing contact with the adjustment ring in the box. This plug can be used on three-wire systems in which the barrel is employed as the neutral conductor. In this case the third pin can be used to carry current, and the pressure between it and the others will, of course, be half that between the two live conductors. There are numerous other interesting features of the "Kalkos" screwed tube system, but we would recommend our readers to apply to the Sun Electrical Co. for catalogue No. 201, section C, for more detailed information.

IMPERIAL SUCTION CLEANERS.

We omitted to mention in our description of the Imperial suction cleaner last week that the small motors employed in connection with these cleaners are suitable for direct-current and alternating-current circuits, the latter of any frequency. The motors are wound for 100 volts. A lamp resistance is inserted on 200-volt circuits. We understand that the recent tests in a West of England city were direct-current supply at two voltages and alternating-current supply at two voltages and two periodicities. The motor of the cleaner was switched from one circuit to the other and operated with every satisfaction. This is somewhat of a critical test, but it should materially assist station men and electrical contractors in pushing this useful device. The motor is, of course, of the commutator pattern, and runs at the extremely high speed of 10,000 revs. per min.

ELECTRIC THEATRES.

We are constantly being reminded of the popularity of the electric theatre. Not only are these places of amusement to be found in practically every town, but there are out-of-the-way places almost without number in which they have been erected. This fact is no doubt indicative of the profit-bearing nature of this class of investment. But it is interesting to note how the electrical engineer has been able to contribute to the economical operation of the illuminating side of these places of amusement. The British Westinghouse Co. has prepared a brochure entitled "The Cinematograph Theatre," which sums up the situation on the opening page. Shakespeare's Iago remark "Put money in thy purse" is inscribed on the title page, with a sub-note to the effect that "this booklet tells you how." The booklet explains how the main source of electricity can be made to operate a motor-generator which will supply a bioscope lantern at a low voltage and thereby save the wasteful expenditure of many kilowatt-hours in resistances. These motor-generators are made up for alternating-current or direct-current supply, and they are worked out on highly efficient lines, also they run at a high speed and occupy a minimum of space.

Certain figures are given which explain the economy of the motor-generator. A 100-volt circuit must be reduced to 60 volts for the bioscope arc. That is 40 volts, with a current of, say, 60 amperes must be absorbed in the resistance, representing about 2½ units an hour. With energy at 2d. this is about 5d. an hour loss. Where the price is higher the loss is proportionately greater. In the case of a 200-volt supply the situation can only be summed up as it is in the booklet "dead loss," or in round figures 1s. 8d. per hour. If these losses are spread out for an extended period, on a rough calculation a sum of upwards of £200 will be expended in heating resistances. If these figures do not compel the bioscope manager to adopt the motor-generator it is difficult to understand what will. The brochure proceeds to describe the Westinghouse bioscope standard equipments, together with the necessary switchgear. Stand-by plant, in the shape of emergency resistances which can be switched on in case of the failure of the motor-generator, is also referred to.

Where a public supply of energy is not available the management must have recourse to either gas or petrol-driven dynamos, and in the booklet a brief description and illustrations of these units are given. Views are also shown of a number of cinematograph theatres in which Westinghouse equipment has been installed. Interested electrical engineers and contractors should apply for Special Publication No. 7,974/1. We understand a copy of this will be forwarded.

"ONEWATTS" AND AUTO-TRANSFORMERS.

A range of 55-watt "Onewatt" drawn tungsten lamps for high and low voltage circuits will soon be on the market. These lamps are of the same quality as the other sizes of "Onewatts," which are specially suitable for street lighting on account of the robust nature of the filament. They may be used for either alternating or direct-current circuits. They are being supplied in the same size bulbs as tantalums of the corresponding voltage and candle power. The price for 100 to 130 volt lamps in pear-shaped bulbs is 2s. 9d. each, and for 200 to 250 volt lamps 3s. 9d. each; round bulbs 3d. extra. The discounts and selling conditions are identical with those in force.

The new "Onewatts" can be supplied with either B.C. or Edison screw caps at the same price. We understand that Messrs. Siemens Bros. Dynamo Works have large stocks on hand, and orders can be promptly attended to. Lists dealing with these lamps will shortly be issued.

We have also to acknowledge from the same source receipt of a pamphlet dealing with auto-transformers for tantalum, "Onewatt" and other metal lamps. These are offered in sizes from 125 to 8,000 watts, and also a line of balancing, double-wound and bell transformers.

TURBO-BLOWER TEST.

At the invitation of the British Westinghouse Company a large number of managers of iron and steel works and others interested paid a visit to Trafford Park on Monday and Tuesday, May 29th and 30th, to inspect the test of a mixed pressure turbo-blower for operating in connection with blast furnaces. The blower has a capacity of 25 c.f. of free air per minute against 8 lb. to 10 lb. pressure. Considerable interest was shown by the visitors in the test, and every facility for inspection was afforded by the Company, the visitors being accompanied by several Westinghouse engineers.

SIEMENS CORONATION ILLUMINATIONS.

When the general catalogue of illumination material was issued by Siemens Bros. Dynamo Works we gave details of the designs and devices which had been prepared for the Coronation. We understand that a large number of buildings have been fitted up with Siemens material, prominent among them being that of Messrs. Woolland Bros., Knightsbridge. On this building there is a splendid array of illumination devices in wood and cut crystal glass, together with coloured transparencies of the King and Queen, and a number of shields, emblems, flags and wreaths. The drapery is also tastefully arranged, and the Bro-ite strip and floral festoons are employed with beautiful effects. The adjoining illustration gives a fairly good idea of the scheme, though, of course, it should be seen illuminated in order that all its pretty colour effects may be appreciated. Each carbon filament lamp as fixed in its Bro-ite strip holder is surrounded by a rosette which gives each individual lamp when illuminated the appearance of a flower. This effect is lost in the detail of the picture, but we reproduce in the top left-hand corner a large scale view of the lampholder.

Among other installations carried out by Messrs. Siemens we may mention Messrs. Mann, Crossman & Paulin, all the City offices of the Royal Mail Steam Packet Co., the Commonwealth of Australia, the "Statist," three branches of Williams, Deacons Bank, Cox's Bank, Gramophone (Ltd.), Brown, Shipley & Co., Shoreditch Town Hall, &c.

The installation work has been sublet to electrical contractors and much the same class of material as at Messrs. Woolland's has been used.

CHEAP STEAM PLANT.

We are reminded of the economies which are possible with the highly superheated form of combined steam plant known as the locomobile, by a new catalogue just issued by Messrs. R. Wolf. This illustrates and describes the latest types of Wolf locomobiles, which we understand are made in various types and sizes up to 800 H.P. With these machines the makers guarantee a coal consumption from 1·2 lb. per brake-horse-power-hour and a steam consumption of 9·7 lb. per brake-horse-power-hour. The company inform us that they have just shipped for Rio de Janeiro two 650 B.H.P. locomobiles. These plants will be installed in the emergency station at Nichteroy. The plant is of particular interest in that the engines are direct connected to the alternators which they drive. These machines are of the British Thomson-Houston make, and each has a capacity of 400 kw.

IFS AND QUERIES.

Will the Electro-Harmonic Society change its name for the 1911-12 season ?

Will the Publicity Committee survive the stress of the Olympia Electrical Exhibition ?

We have standard varnish, standard oil, engineering standards and standard bread, why not a standard metal lamp ?

Why are our gas contemporaries lacking in humour ? Can it be because they must now work at high pressure in order to make a living ?

Mr. Pain, the pyrotechnist, recommends gas as a Coronation illuminant because of its flickering proclivities. Has Mr. Pain forgotten that "all that flickers is not gold" ?

Will the automatic telephone be fitted with a tablet for the writing down of expletives ?

Are YOU Selling The IMPERIAL Vacuum Cleaner?

One firm in the trade sells 24 of these machines a month.

Exclusive Features.

50 per cent. more efficiency than any Cleaner at an equal price.
Same motor runs on either D.C. or A.C. 90 to 250 volts and 25 to 100 cycles.
Self-aligning bearings,—armature cannot get out of alignment.
Entire machine weighs only 9 lbs.
Greater cleaning surface than any other portable Cleaner.
Absolutely guaranteed against wear and defects.

Here is one of the fastest selling specialities ever introduced to the trade. A self-contained Suction Cleaner of tremendous power. As small as a carpet-sweeper As powerful as some of the Cleaners that cost hundreds to instal. Every Hotel, every Boarding-house, every Private House that uses Electric Current will use this new Cleaner. This is a splendid opportunity for the Electrical Trade to get some of the business that is going in Vacuum Cleaners. We have a plan to outline that will enable you to get the bulk of the Vacuum Cleaner business in your district. Special agencies will be granted in certain districts. Write to-day, for particulars and prices.

Light and Portable—
yet the most effective Cleaner on the market.

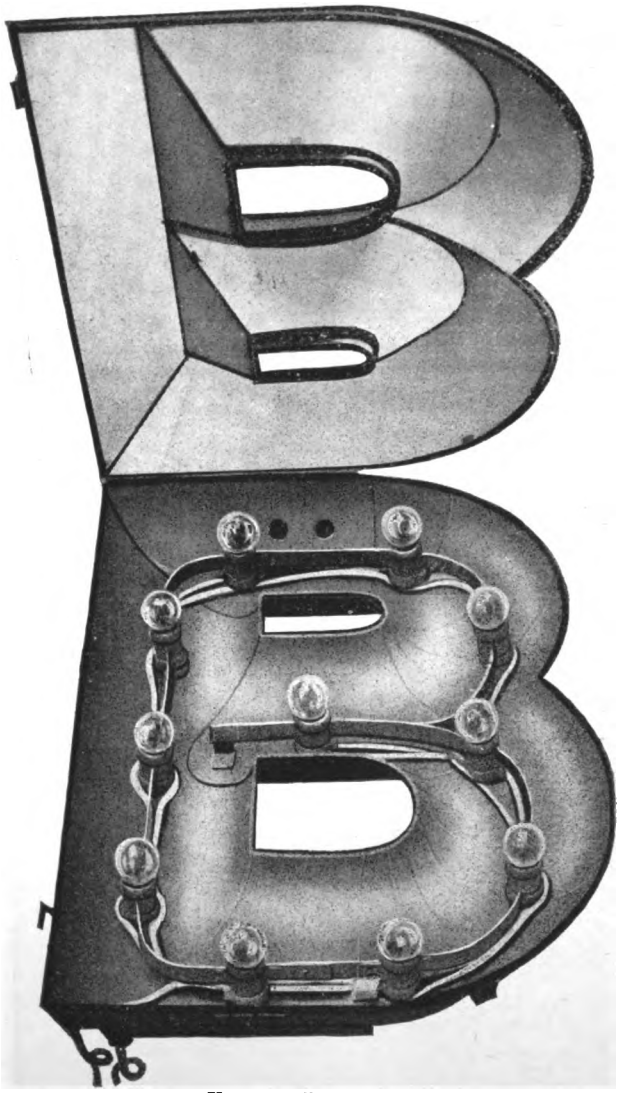
NEW DAY AND NIGHT SIGN LETTER.

We have received advance particulars of a new pattern of illuminated letter which can be made up into signs and figures for display advertising, &c. It is known as the "Diamond" letter, and it will be seen from the illustrations accompanying this article that by reason of the shape adopted the letter is clearly visible from all angles. This has a particular advantage, as it admits of the sign being placed directly on the wall surface, where it can be securely fixed and presents a minimum of wind resistance. The letters are made up on an outer casing of enamelled metal, with front panels of opal glass. These panels are hinged, and can be opened to give access to the lamps inside, and also to admit of the cleaning of the glass. The lamp-holders themselves can be mounted in a substantial manner in the interior of the letter, and there is the further advantage of their being under cover and thoroughly protected from the elements.

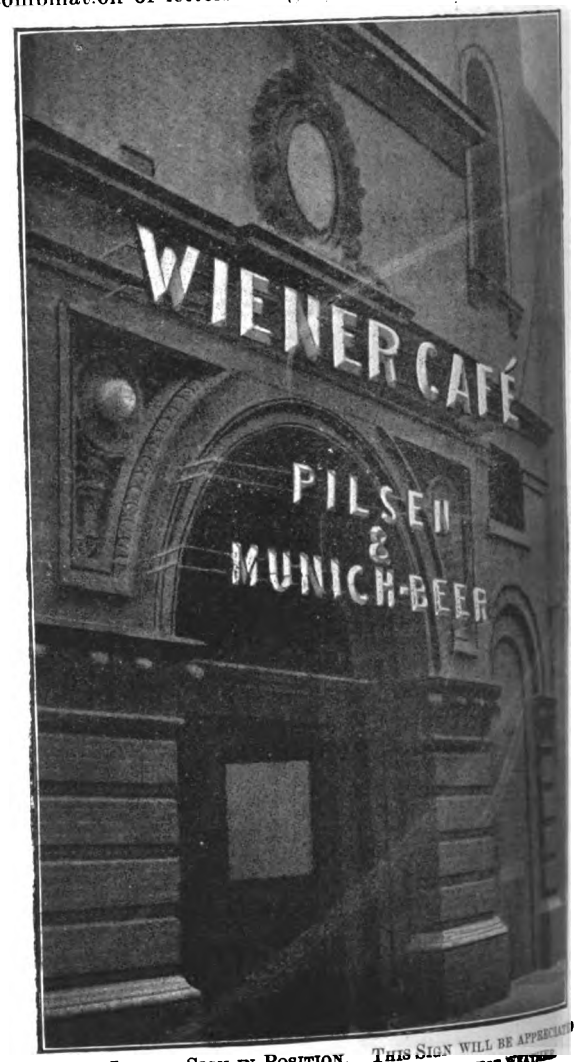


General View of Diamond Letter.—Open.

In a pamphlet just issued describing and pricing this interesting letter it is stated that, compared with wooden letters, the illumination can be carried out with one-half the candle-power. This is due to the design of the back of the letter affording an ample and efficient reflecting surface. The light from the lamps is also utilised to the fullest extent for the illumination of the letter, and none is wasted on the surrounding walls. The all-metal construction also reduces the chances of leakage, as there is practically nothing to absorb moisture.

The interior of the opal face of the letter, and in fact the exterior also, can be easily cleaned with a damp cloth. Any combination of letters or figures can be made up. Coloured lamps may be introduced and various effects obtained by the use of a suitable switch.

The wiring is arranged for 14-volt metal or carbon lamps and these are connected up in series parallel. The lamps in the letters are in parallel and the letters themselves are placed in series. The "Diamond" letter is made up in sizes varying from 12 in. to 48 in. high, and full particulars will be supplied by the makers, Messrs. Hill & Harrington, Great Portland street, London, W.



Diamond Letter Sign in Position. This Sign will be appreciated by our readers during the present spell of hot weather.

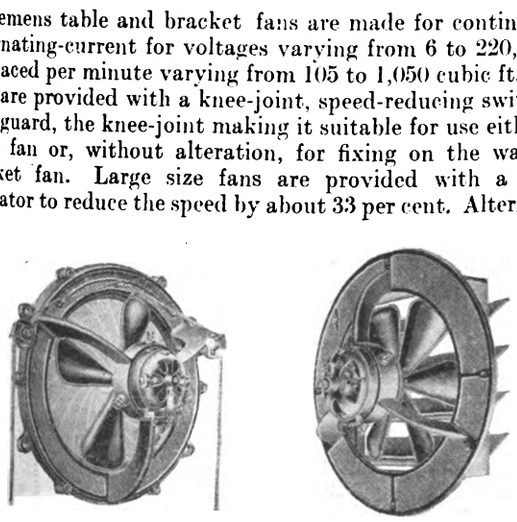
SIEMENS FANS.

Siemens table and bracket fans are made for continuous or ternating-current for voltages varying from 6 to 220, the air isplaced per minute varying from 105 to 1,050 cubic ft. These ns are provided with a knee-joint, speed-reducing switch and ire guard, the knee-joint making it suitable for use either as a ble fan or, without alteration, for fixing on the wall as a racket fan. Large size fans are provided with a special gulator to reduce the speed by about 33 per cent. Alternating-



Siemens Porthole Fans.

rent fans are provided with induction motors which run ntly, and, having neither commutator, slip-rings nor shes, can be left running for considerable periods without endance. Fans for installing in damp situations are pro-ed with special insulation.

A line of standard porthole fans is also made by Siemens os. Dynamo Works, and types of these are illustrated here-h. They are supplied for alternating-current and direct-rent motors and both horizontal and vertical positions. damp situations and acid-laden atmospheres a centrifugal e of fan is recommended, as in this case the moving air does not make contact with the motor. Fans and motors for every class of ventilation can be supplied, and full details will be forwarded on request.

METAL TUBOLITES.

The system of lighting introduced some years ago by the Linolite Co. has made considerable headway since its inception, and particularly so since the company introduced the metal filament into the system. 25-volt Tubolite lamps have been on the market for nearly three years, but we understand that the company now has a stock of 100 to 125 volt lamps, and that they are prepared to make immediate delivery. The candle-power of these lamps is 12, and the efficiency is stated to be 1·5 watts per candle. There is no difference in the price per foot of the complete fitting over that which obtained with the low-voltage lamps, so that there will be no complication in the matter of prices. A descriptive booklet has been issued by the company, and this gives full particulars of the Tubolite lamps and their fittings. In this we note that the Civil Service Supply Association has installed some 200 25-volt metal Tubolites, which have been running since December, 1908. Boots Cash Chemists are also large users of the same pattern of lamp.

DUST EXTRACTOR FOR COAL MINES.

A demonstration of a new apparatus for extracting dust from coal mines was given recently by Mavor & Coulson, Glasgow. The plant has been designed in view of the fact that recent experiments have proved that explosions in collieries are not gas explosions, but are propagated through the mine by coal dust. The dust extractor consists of a combination of pressure air jets directed upon the surfaces to be cleaned

in order to raise the dust from them and the simultaneous withdrawal of the dusty air by suction. The apparatus is operated either by an electric motor or by compressed air where that source of power supply is used. Its main parts are a bell-shaped mouthpiece, close to which is a nozzle carrying a jet of pressure air, a means of obtaining the jet of air for disturbing the dust, a means of obtaining suction for with drawing the dust, and a filter for retaining it and allowing the air to escape. The apparatus may be adapted for searching deep crevices and for removing dust from above and around timbers, The plant will shortly be sent to a colliery in South Wales.

THE "ELECTRIC ARC."

Now that the days of electric propulsion for ships has arrived we shall no longer refer to a vessel as s.s. "Polly Ann," or whatever its particular name may be; it will have to be e.s. "Polly Ann," although this will not sound anything like so euphonius. In our special issue, "Marine Electrical Practice," published last year, we included an article on the alternating-current system of ship propulsion invented by Messrs. Mavor & Coulson. We have now received from this firm a brochure describing the equipment of a 50 ft. vessel with this system of propulsion. She has been built by McLaren Bros., Dumbarton, and is certified for the carrying of 50 passengers.

OSRAMS AT TORQUAY.

When the electricity works were opened by the Corporation of Torquay nealy 13 years ago the lighting of the Torbay-road and the High-street from Torre station to the harbour was entrusted to open-type Crompton arc lamps. These were supplied in series for three Ferranti rectifiers,and until just recently have been running continuously since they were started. The illumination was probably one of the best examples in street lighting by open-type arcs which could have been met with in this country, and no doubt the clearness of the atmosphere and the position of the lamps, particularly along the sea front, round Torbay, had a good deal to do with the result.

After so many years of yeoman service these arc lamps have had to give way to the high candle-power metal lamp. We give an illustration of a portion of the street lighting in the neighbourhood of the inner harbour, showing the 1,000 c.p.

STREET LIGHTING AT TORQUAY WITH 1,000 C.P. OSRAM LAMPS.

Osram lamps now in use. By the installation of these lamps the rectifier plant—which is now, of course, obsolete—has come out of service. The labour item for attending to these machines and also that formerly necessary for the trimming of the arc lamps, has also been saved. Mr. Salt, the borough electrical engineer, is, we understand, particularly pleased with the economies which this alteration has effected, and the Town Council is also very satisfied with the lighting of the streets.

THE ELECTRICIAN COMMERCIAL AND INDUSTRIAL SUPPLEMENT.

C. & I. Supplement No. 88.] JUNE 9, 1911. [Gratis to Subscribers.

GLASS GLOBES FOR STRIP LIGHTING.

In Coronation illumination material such as continuous lengths of lighting strip the effect of the small lamps can be considerably enhanced by the use of glass globes. The Sun Electrical Co. are offering these glass globes to clip over their "Suncolite" lamps or any other form of lighting strip. The globe is held in position by small clips as shown in the illustration. They are supplied in two sizes 4½ in. and 6½ in. diameter,

GLASS GLOBE FOR SUNCOLITE AND OTHER STRIP ILLUMINATING MATERIAL.

and are stocked in five colours—red, white, blue, green and amber. The globe is easily fixed, and from samples shown to us in the Sun Electrical Co.'s show-room the improvement in the lighting effect is very marked. The globes look very well at intervals of about 3 ft. to 6 ft. with the smaller lamps in between. Contractors and central station engineers should make early application for these globes before the stock is exhausted.

ICE MAKING.

A cool subject for the sultry weather! Central station service should benefit in these sweltering days, for although people do not want light or heat they are crying out for fans and ice. The electric fan is sufficiently well known now to be demanded by a gasping public when the temperature gets into the "eighties," and contractors and the trade generally are able to cope with the demand.

An entirely different class of service is that given to the electric ice-making plant. This kind of load is not cultivated "on this side" like it is in the States, where a flourishing business in small ice-making outfits is done. These are usually just big enough to be driven by a small motor, and the additional load is welcome enough to the central station. We believe that many of the smaller electricity plants in America are able to fill in the valleys of the summer load by giving a supply to ice-making plants. As a rule the load is a 24-hour one during the season, because the heat is maintained and so also is the demand of the public for ice.

Here in this country there are ice and cold storage plants which do a great business all the year round. The foods imported to our great shipping commercial centres need preservation, and only a low temperature will assure this. These storages generate their own energy and compete in some measure with the smaller plants which hotels, restaurants, &c., might otherwise instal. There is, however, a ripe field for central station service if the publicity men will chase round and garner the harvest. This must be particularly the case in types of small towns which are remote from an ice supply, and where very large quantities of ice are not really required. Perhaps those station men who supply cold storage and small ice-making plants can give us some information on this subject.

WATER-LEVEL INDICATORS.

In a recent issue we remarked upon the publication of a new list by Siemens Bros. & Co. in which their water-level indicating

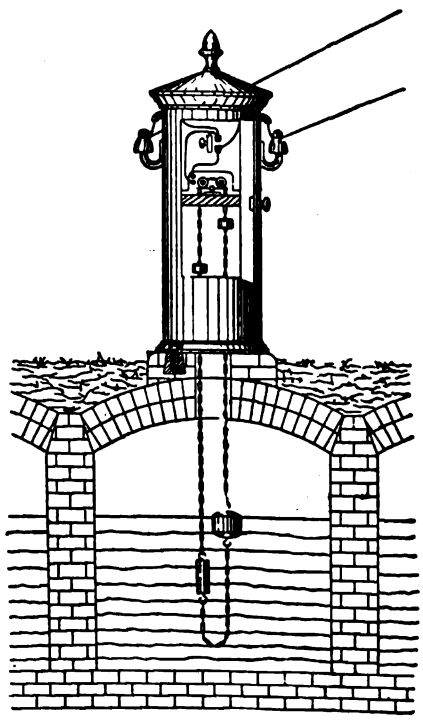

FIG. 1.—WATER-LEVEL TRANSMITTING PILLAR FOR USE OVER UNDERGROUND RESERVOIRS, ETC.

appliances were described in detail. We are now able to illustrate patterns of this apparatus. For purposes of water-level indication a transmitter, indicator and battery are necessary. The transmitter, which is always in a damp situation, is provided with a watertight case, which adequately protects the contacts from the effects of oxidation. Fig. 1 shows a pattern of transmitter which is enclosed in an iron pillar box and is suitable for mounting over an underground reservoir. The transmitting wires are arranged on insulators on the top of the pillar, and a lightning arrester is also fitted. In Fig. 2 is shown a level indicator with recorder which is intended for a terminal station. The apparatus is contained in a polished walnut case, which also is fitted with train with large dial, plate lightning arrester for two lines, bell-recording device and drum. This apparatus is supplied for levels of 10 ft. and 20 ft., and the clockwork can be wound for one or seven days according to the size used. For an intermediate station the apparatus is slightly modified.

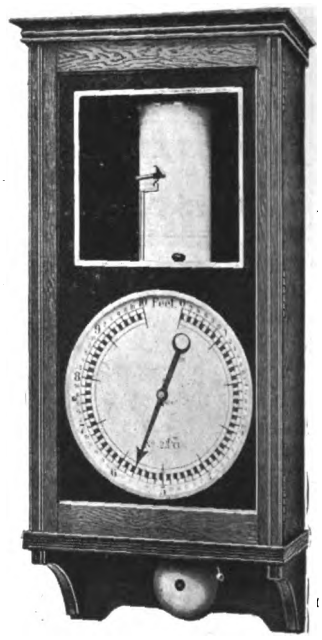

FIG. 2.—WATER-LEVEL INDICATING AND RECORDING INSTRUMENT.

In the catalogue to which we have referred above a line of bell switches with auto-replacement is described. These can be employed on waterworks where the minimum or maximum water level of the reservoir is maintained over a long period. In such cases it is inconvenient if the corresponding bell signal is continued over the whole of this time. The switches in question permit of the disconnecting of the bell by sharply depressing a button. In the same list a series of portable telephones with buzzer call, &c., is described.

FAN PUBLICITY.

"Phew! Ain't it 'ot, Bill? What?" This has been the cry of the last few days, and there should have been a boom in electric fans in consequence. The Electric Supply Publicity Committee in their new publicity issue are giving a special fillip to electric ventilating and cooling.

In the fan poster the breezy and exhilarating effects of an electric fan are depicted. An old sea captain of jovial aspect is caught in the full blast of an electric fan at top speed, and, to judge by his countenance, he thinks it only a trifle second best to a "sou' wester." To follow up this there is a 6 pp. folding booklet, illustrating fans for various uses, and with an illustra-

ELECTRICITY SUPPLY FAN POSTER.

tion on the cover which should commend these fans to all homes where comfort is a consideration. This booklet is suitable for sending out with the June quarter's accounts or with the receipts. There is also an adhesive label included which is a miniature of the poster, and which may be useful for attaching to correspondence.

The issue also includes an ironing folder, which is adjusted to go in the ordinary correspondence envelope, and should be useful for pushing this important side of electricity supply.

The Committee have also done a little catering for the trade in the way of a circular on electric signs. The circular should appeal particularly to shopkeepers, and the arguments are driven home with a number of illustrations.

MARELLI OSCILLATING FANS.

Electrical contractors and central station engineers will be interested in a new leaflet, L.B. 11/16 of their 1911 season fans, which Ercole Marelli & Co. are putting on the market this season. The fan is of the oscillating type, and can be supplied for alternating-current and direct-current circuits. This fan is of the convertible type—that is, it can be used as a desk or bracket fan. Interested readers should make application to the offices of the company, 26, Garlick-hill, London, E.C.

THE DIAMOND SIGN.

Messrs. Hill & Harrington, whose diamond sign we described in last week's issue, write us to the effect that while they are the patentees and owners of the Diamond letter, those shown in the illustration of Wiener Café were supplied by them through S. J. Smith & Co., 46A, Holborn-viaduct, London, E.C.

WESTINGHOUSE TURBO BLOWER.

We stated in error in last week's issue that the turbo-blower which a number of colliery engineers inspected recently at the Westinghouse Works had "a capacity of 25 c.f." This should, of course, have read 25,000 cubic ft.

BRIMSDOWN OUTING.

Over 500 "Brimsdownites" and their friends saw things in a better light last Saturday at Hastings, the occasion being that of the third annual outing. The large party left Brimsdown in a special train at a very early hour, and Hastings was reached at about 8:30. The heat of the sun was tempered during the morning by a sea fog, but the afternoon was superbly fine. Luncheon was served in the Royal Concert Hall, and it was a particularly gay company that sat down to a most enjoyable repast. Mr. E. Scharrer, the genial general manager of the Imperial Lamp Works, was in the chair, and on rising was accorded a great reception, an incident which abundantly testified to his popularity. His health was proposed in pleasing terms by Mr. Haynes, of the Nottingham office, who dealt particularly on Mr. Scharrer's activities at the works, and also upon his kindly treatment of those employed there. After lunch the party broke up, and generally amused themselves in the neighbourhood, there being no set programme for the afternoon. The officials and their friends much enjoyed a char-a-banc ride to Battle Abbey, and returned in time to join the special back to town. The outing was voted a huge success. The company also included Mr. J. J. Chiswell (the sales manager), and Mr. M. Brinckmann. The latter carried through the whole of the arrangements, and was the recipient of a special vote of thanks for his efforts. But for the fact that the outing clashed with the Whitsun Holiday, there would have been 600 present, this number being employed at the works.

IFS AND QUERIES.

If the N.T.C. is not transferred to the G.P.O. at the year end, will the P.M.G. be present at the next Annual Dinner?

Will the Inst.E.E. arrange its summer meeting before or after the I.M.E.A. next year?

Will Mr. Hope Jones fit his clocks to all the Coronation Arches?

What has become of the sea serpent in the daily press these hot days? Perhaps it is another victim of "the fusing of electric wires"?

NEW TRADE LITERATURE.

ELECTRIC BELLS AND TELEPHONES.—The new bell and telephone list of Falk, Stadelmann & Co. is a publication of over 100 pages and contains a vast amount of information on electric bells, pushes, indicators, bell pulls, wires and staples, wiring accessories, wet and dry batteries, switches, telephone instruments of all kinds, portable electric lamps, &c. We do not remember having seen so comprehensive a catalogue dealing with this subject. We should recommend every electrical contractor to make early application for a copy.

SERIES STRIPLITE.—The Lamp Department of the Electrical Co. is offering series striplite for coronation illuminations at a special price of 1s. per point, which includes the lamp. Striplite is made up with porcelain holders 5 in. apart supported by flexible metal bands and complete with 2 c.p. 14-volt pear-shaped lamps which can be supplied clear, frosted or coloured.

GRAPHITIC CARBONS.—Geipel & Co. are sending out two lists dealing with their Graphitic carbon brushes for dynamos and motors, and also a list describing and pricing Henrion carbons. This last-mentioned list contains a number of interesting photographs of various kinds of arcs, flame type, open, enclosed, searchlight and welding, which are of considerable interest.

THE "LIGHTNING" GRILLER.

An interesting addition to the ranks of electric cooking and heating appliances has recently been made in the shape of the "Lightning" griller. This has been designed for pressures up

FIG. 1.—ELECTRIC GRILL.

to 250 volts, and is being introduced by Siemens Bros. Dynamo Works. In the adjoining illustrations Fig. 1 shows the electric heater, which is a detachable unit, and is made up of copper or aluminium with hard wood carrying handle. The grid and cooking dish and tray shown in Figs. 2 and 3 are for use in conjunction with the heater. When the food is to be cooked it is placed on the grid, which in turn is placed over the cooking dish

FIG. 2.—GRILL PLATE.

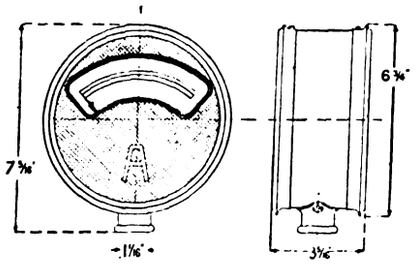
or tray. The heater is then placed on top and the heat is directly applied to the meat on the grill. Cooking commences as soon as the heater is turned on. We understand that two pieces of toast can be made in five minutes with an energy consumption of $\frac{1}{30}$th unit, or 1 lb. of sausages will be fully cooked in the space of 15 minutes, $\frac{1}{10}$th unit being required to furnish the

FIG. 3.—COOKING DISH AND TRAY.

requisite heat. We are informed that the grill is quite simple in operation, and that it can be cleaned thoroughly after use with a minimum of trouble. Full details are contained in a price list just issued.

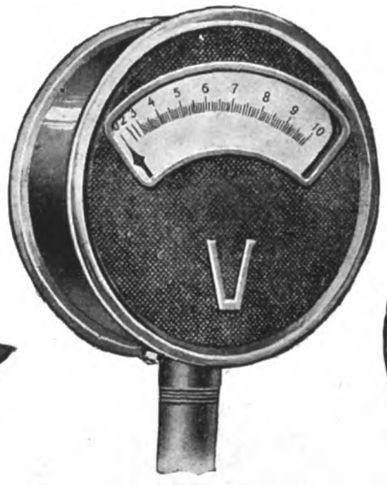
"ADNIL" INSTRUMENTS.

Particulars have been issued by the Adnil Electric Co. of a line of electrical instruments which they have put on the market. These instruments are made for alternating-current and direct-current circuits, and are of the electro-magnetic type. The makers state that the effects of wave form and frequency in the alternating-current instruments are comparatively



GENERAL DIMENSIONS OF AMMETER.

slight, also temperature errors are practically negligible. The energy consumption of the instrument has also been reduced to a minimum. The oscillations of the needle are damped by an air dash pot, and all moving parts are enclosed in dustproof cases. At the same time the coils themselves are well ventilated. The moving spindle is mounted in jewelled bearings at



FRONT CONNECTION VOLTMETER.

OPEN SCALE AMMETER.

both ends. The standard finish of these instruments is black enamelled case with polished nickel front rim. The instruments, types of which are illustrated herewith, are intended mainly for switchboard use, and can be supplied both as regards

ammeters and voltmeters with front and back connections. List AE. 58, just issued, gives full details of these instruments. They can be divided into two main types, model BN, with 6 in. dial, and model K, with 4 in. dial. In the model BN type instruments are made as voltmeters for pressures up to 750 volts, and as ammeters for currents up to 800 amperes, without transformers. The makers state that voltage and current transformers are only required for instruments above these pressures and capacities. It will be seen from the illustrations that the scale readings are open and distinctive, though these can be made suitable for any special requirements.

B.T.H. ELECTRIC KETTLE.

Particulars have reached us of a new pattern electric kettle which is being introduced by the British Thomson-Houston Co. The feature of this kettle is the heating element. This is made up of calorite wire wound on a mica former, which is then enclosed between two cast-iron plates and insulated from them by mica discs. This should make a particularly useful element, as calorite has a melting temperature of 2,800°F. This means that the heating element is thermally indestructible under service conditions. Of course, if the kettle is left on circuit dry, the bottom would be badly burned, but the element itself would not be destroyed. The element can be removed and readily replaced by the user if it is desired to connect the kettle to a circuit of different voltage.

The body of the kettle is of solid copper, highly polished and finished. The interior is tinned to prevent corrosion, and the normal capacity is two pints; at the same time $2\frac{3}{4}$ pints of water can be got into the kettle. The rating is 500 watts, and the kettle will boil two measured pints of water at 60°F. in $17\frac{1}{2}$ minutes. The kettle is listed at 20s., and is offered in four sizes, giving voltages from 95 to 250. Price list No. 298 gives full particulars and also details of the accessories and separate parts of the kettle.

MORE SIEMENS CORONATION INSTALLATIONS.

We are informed by Messrs. Siemens Bros. Dynamo Works that, in addition to the contracts for complete Coronation schemes to which we referred in our last issue, they have secured a further batch of orders. As in the previous cases, the work will be sublet to electrical contractors. The customers include the Commerical Union Assurance Co. for their City and Pall Mall offices, Kensington Town Hall, Kensington Library, North Kensington Branch Library, Kensington Baths, and Messrs. Carreras (Ltd.), Arcadia Works, City-road.

HENLEY'S FLEXIBLES.

A particularly attractive catalogue is being issued by Messrs. W. T. Henley's Telegraph Works. The list is noteworthy from the manner in which the cover has been arranged and the matter itself displayed. We understand that this is the first time the Company has issued a separate list dealing with their flexibles, the data and prices for this particular product having previously been embodied in their V.I.R. cable list. There can be no doubt that this separate publication will be much more convenient and will be generally appreciated. We understand that several classes of flexibles have been added to the new list, and amongst these we may specially mention what are known as Home Office flexibles, which are braided with specially hard cord which affords as effective a protection as metallic covering; at the same time it obviates the necessity for earthing the protective covering.

A "LOW FREQUENCY" ARC LAMP.

Consumers on low periodicity (anything below 40 periods) alternating-current circuits will be interested in a new form of arc lamp which possesses advantages over the ordinary enclosed arc lamp actuated by a coil. The construction is of the simplest, and little trouble is experienced in making adjustments, and hence unskilled labour can be employed for cleaning and trimming. The regulation is based on an improved form of the thermo-expansion principle—a strip of special alloy being used to operate the essential working parts. Increased reliability is secured by the absence of a dash pot. A high power factor is also maintained in the circuit because the lamp has practically no self-induction. This is most important when a large number of lamps are employed, because the P.F. may be appreciably decreased owing to the presence of coils and relatively large masses of iron.

On 200-440 volts it is recommended that the lamps be run in series-parallel with a transformer. This not only makes for steadiness and reliability, but each lamp is independent, and can be switched on and off regardless of any other lamp connected to the same transformer. This method, too, renders a substitutional resistance and auto cut-out unnecessary when a number of lamps are run on a high-voltage circuit. The lamp is made by the Foster Engineering Co., Wimbledon.

THE ELECTRICIAN COMMERCIAL AND INDUSTRIAL SUPPLEMENT.

. & I. Supplement No. 89.] JUNE 16, 1911. [Gratis to Subscribers.

PEEBLES A.C. LARGE TYPE MOTORS.

The dynamo electric products of Messrs. Bruce Peebles &). are well known, and considerable interest attaches to their test catalogue, which has been prepared in order to describe e Peebles large size alternating-current motors. The catalogue is divided into two parts, describing (1) the dplate type motors, in which the bearings, either two or ree in number, are mounted on a bedplate, which also forms base for the motor body, and (2) the self-contained type in hich the bearings form part of the motor case. e illustrate one of these latter machines, and it ll be noticed that a particularly compact type of nstruction is obtained in this pattern. The otor has been designed to meet the require-nts of industrial service, where the space al-ted to the power agent is, more often than not, ited. The motor has been designed for the ving of fans, pumps and other types of industrial chinery. The general electrical features are ilar to the firm's standard machine, the dis-tive difference being in the arrangement of the rings and the slip-ring gear. The bearings are he pedestal type and are carried on suitable sup-ts cast as part of the end hoods. This arrange-nt places the bearings well within the limits of body of the machine. It also admits of the rings being fixed in a convenient and accessible tion. The machine illustrated is of 150 B.H.P. was designed for operation on a 3,000-volt uit.

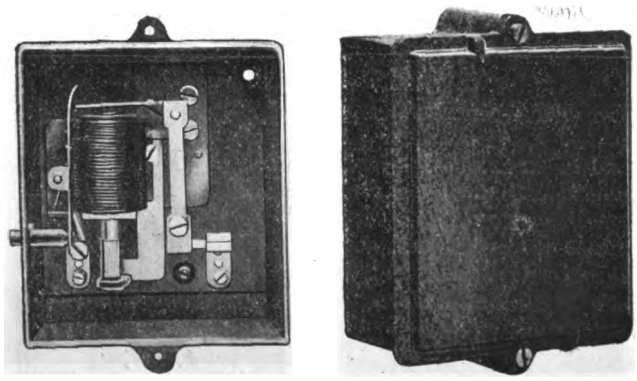
ADNIL LIMIT SWITCHES.

In certain classes of consumers' installations a meter cannot profitably be installed, and a fixed charge for a certain number of lamps is made. In order to prevent the consumer exceeding the agreed number of lights some current-limiting device is used. Its functions should be to first warn the consumer of the excess and then to interrupt the supply altogether if no reduction in the load is made. We illustrate an interesting current-limit switch with which the Adnil Electric Co. has made



THE ADNIL SWITCH WITHOUT AND WITH COVER.

considerable headway. It is constructed for alternating-current and direct-current circuits, has a current range of from 0·2 to 6 amperes. It is a simple series solenoid device and previous to the opening of the circuit it "flickers" the lights, thus giving visual warning of its likely operation. It is enclosed in a cast-iron case which may be sealed by the supply authority after the switch has been adjusted for the desired current. The switch is made single pole only.

These switches should enable supply stations to make profitable fixed contract rates with small consumers for a few metal lamps. For consumers installing, or requiring to burn, at one time, only a few lamps, the running cost to the station is small. The lamps may be burned one hour or 3 to 6 hours per day or more, because the rates fixed for each consumer per lamp per annum will cover the fixed standing charges and the profit for the supply authority.

There are considerable advantages with this system. The consumer knows how much he has to pay per annum, and the supply station also knows how much it is to receive. The costs of account checking and meter reading are therefore avoided.

The general failure of supply stations to obtain small consumers in competition with gas and other forms of lighting is largely due to the fact that the small consumer has a persistent idea that electric lighting is too expensive for him. With this system he will be found willing to pay a fixed sum per annum for all the electricity he uses.

Where a supply is given for heating and cooking, power &c., on the ordinary system it is merely necessary to have a lighting and power circuit with a limit switch on each. One of the chief applications of these switches, however, is for lighting circuits. The Adnil limit switch corresponds, in great measure, to a slot meter in its working. The cost of the switches is only about 9s. each net for the small sizes up to 3 amperes in cast-iron cases. The most useful size is probably that for adjustment of 0·2 to 1 ampere limit. This would provide for a maximum 3 to 14, 16 c.p. metal lamps installed on a 220-volt circuit and all alight at one time, and be suitable for, say, the installation of one-and-half times to twice that number of lamps by the consumer.

This cost of 9s. per switch is only about one-third to one-sixth the cost of a meter for similar requirements. The system of charging by contract rates with limit switches is especially applicable to cottage and artisan dwellings and is well worth the consideration of central-station engineers seeking to extend their supply in these directions.

The fixing of the contract rates depends of course on the capital and standing charges and running costs of the respective supply station and the kind of lamps used, and is a matter for the decision of the station engineer. We understand that sample switches will be supplied to order.

A further application of Adnil limit switches is in connection with the well-known Therol system of electric water heating by contract. When the current is switched off the heater or to the lights, &c., it is necessary for the supply station to know that a certain current limit or wattage will not be exceeded by the consumer. For such installations meters would, of course, be considered little else than a superfluous expense both to the supply station and to the consumer.

THE C.W. TESTING SET.

A new instrument is being put on the market by Messrs. Elliott Bros. under the above title. These testing sets are of the dynamometer pattern, and, with the addition of transformers, are suitable for use on alternating current, or with shunts they can be used on both alternating and direct-current circuits. They are made in several distinct combinations. The construction of these instruments is such as to make them practically independent of the wave form and periodicity of the circuit on which they are used, as well as being free from errors due to temperature variations. They are spring-controlled, with balanced movements and dead-beat action, as

all the parts are carefully selected and, where necessary, aged to secure permanency of calibration. An automatic clamping device is fitted to protect the instrument in transit, and, in common with all instruments of Elliott manufacture, a zero device is fitted to enable the pointer to be accurately adjusted to zero without breaking the seals.

The makers recommend this type of test set where instruments of maximum precision are required. Full details and prices in section G, list 11.

"ONEWATTS" AT MARGATE.

The contract for the supply of Tantalum and "Onewatt" Lamps, together with special fittings for the Fort Pavilion, Margate, has been placed with Siemens Bros. Dynamo Works. This pavilion is a magnificent new concert hall, and the fittings have been specially designed in order to obtain an artistic illuminating effect. In the centre of the main hall there will be four cut crystal glass electroliers, each having 6 in. to 9 in. projecting arms, with 10 c.p. to 30 c.p. lamps in each. There are also four similar cut crystal glass electroliers in which 8 c.p. to 50 c.p. Tantalum lamps are installed. Under the balconies there will be 14 holophane bowl fittings, each having three projecting arms; in the central bowl a 200 c.p. "Onewatt" lamp will be installed, and 50 c.p. Tantalum lamps in the holophane reflectors on each of the projecting arms.

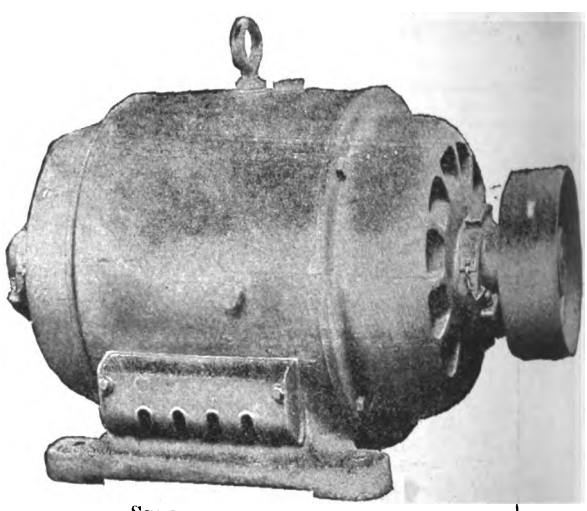
Under and over the gallery there will also be four holophane bowl fittings similar to the above but without projecting arms, and 200 c.p. "Onewatt" lamps will be installed. On the stage ceiling there will be 10 holophane bowl fittings suitable for taking 1 c.p. to 200 c.p. "Onewatt" lamps, and it is expected that an effective illumination will be obtained by these means.

Holophane fittings are also being supplied for the colonnade and entrance halls. Ornamental brackets with best quality etched shades will be used for the front of the gallery. In the outside entrance hall, torch fittings and flambeaux will be used, whilst for subways and outside steps cast-iron water-tight fittings will be used. For external lighting there will also be 40 cast-iron standards, approximately 8 ft. high, suitable for taking 100 c.p. "Onewatt" lamps. In addition to this, the footlights will be 30 ft. long, being constructed with short iron reflectors, enamelled white inside and black outside. There will also be a quantity of holophane shades and accessories for use in pendants, &c.

The value of the fittings will be £400, and, as mentioned in last week's issue, the total cost, including contracting, will be £729. 15s. The contracting work is placed in the hands of Kingston & Co., Northdown-road, Margate, and when completed this should be one of the most up-to-date installations in the country.

ELECTRICAL CO.'S D.C. MOTORS AND DYNAMOS.

The general merits of the direct-current machines made by the Electrical Co. are set out in a well-prepared price list. The size and style of this will commend itself to contractors and electric-power engineers. The machines listed range in output from the smallest ¼ H.P. to 100 H.P. They are grouped in three different types; N.E.G. up to 2 H.P.; E.G. from 1 H.P. to 6 H.P. and H.N. up to 100 H.P. Standard machines only are described, and to facilitate delivery certain sizes are printed in heavy type, these being available for delivery at a moment's notice. A wide speed range is allowed for on the machines when used as motors. This amounts to 25 per cent. on ordinary motors and considerably more to inter-pole machines.



SEMI-ENCLOSED TYPE MOTOR OR DYNAMO.

As is usual with these motors, either the open, semi-enclosed or enclosed types can be supplied. The design of the machine allows for complete protection of the commutator and brush gear while leaving these readily accessible. As a semi-enclosed machine the motor is fitted with louvred shutters which fit over the end openings on each side of the machine.

The range of motors and dynamos described is entirely new and, we understand, in no way a modification of the older patterns. By the use of the inter-pole fan cooling and simple brush gear the motors will stand up to 100 per cent. overload without sparking. In an efficiency curve (shown in the list) of a 14 H.P. 220 volt 1,100 revs. per min. motor an efficiency of

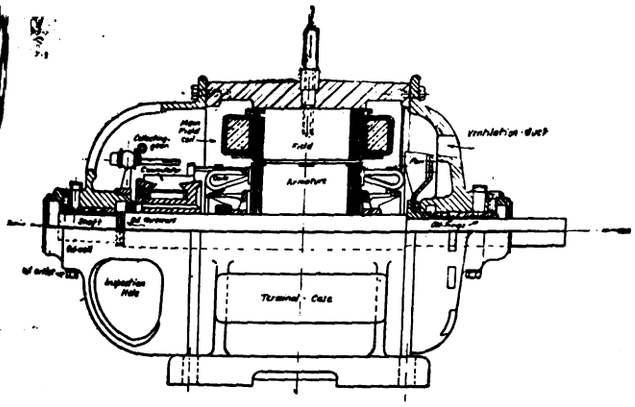
85 per cent. is maintained between ½ load and 50 per cent. overload. At quarter load it is well over 75 per cent. As far as temperature rise is concerned, we understand that the requirements of the Engineering Standards Committee are complied with and that exact figures will be supplied in answer to specific enquiries.



Section Hn Machine.

In addition to the direct-current motors and dynamos referred to above there is a line of motor generators and converters listed and suitable motor starters and shunt resistances for these machines. The list is further commendable for the useful tables which it contains and also for the general instructions regarding running and maintenance.

EXCELLO
FLAME ARC WITH UNIQUE TWO YEARS' WARRANTY

IFS AND QUERIES.

Why is there so little gas illumination in the City of London ? (and elsewhere for that matter). Will our gas contemporaries deign to enlighten us on this point ?

If the figures of the cost of lighting up all the gas illuminations throughout the country could only be published. (The Bank of England cost £20 a time to light up when illuminated by gas !)

Why do not all the metal lamp makers have their annual works outings on the same day at the same seaside place ?

Would it not promote a friendly feeling among the employees and enable the " chiefs " to meet on common ground ?

Will the President and Council of the E.C.A. be invited to the I.M.E.A. Convention—just for a " blow " by the sea ?

What has become of the Kniltic air pump ?

If the use of gas as an illuminant were made a criminal act. (We repeat this in order that it shall catch the eye of some young M.P. who is anxious to champion a new cause in the House ; also it amuses one of our gas contemporaries).

THE DEMAND FOR STRIP LIGHTING.

The doubts expressed earlier in the year that there would be much demand for Coronation material have not been justified by events. In London, which is of course the centre of the celebrations, there has been a rush unprecedented at the last moment for every kind of electrical device, and the trade houses and contractors are evidently up to their eyes in work. It would be interesting to know how many scores of miles of " strip " lighting have been made and erected. There must have been a great run on twin conductor cable to meet the call for this class of illumination material. Small lampholders too will have been frantically made and assembled for the purpose. If any of the makers of this class of material have figures of their output since the beginning of the year we should be glad to publish them if they will furnish them.

STERLING TELEPHONES
The Sterling Telephone & Electric Co., Ltd., 200, Upper Thames Street, London, E.C. Works: Dagenham, Essex.

THE BOSTON ELECTRIC SHOW, 1912.

The superintendent of advertising of the Electric Show which is to be held in Boston from Sept. 28 to Oct. 26, 1912, has favoured us with a prospectus of this interesting exhibition. The letter accompanying the prospectus contains a paragraph which we think is well worth reproducing. It reads: "Our Boston Show will be many times larger than any electric show that has ever been held. We are proud of the start, we are tickled at our progress and we glory in the anticipation of the finish." Here is a pattern for show organisers in this country to follow. It is difficult to beat the average American for enthusiasm, and although "we say it as shouldn't," as Mrs. Brown says, we rather think that what we Britishers lack in initial enthusiasm we make up for in subsequent enterprise. Quite aside from this, however, we find on turning to the prospectus that the Mechanics Building (Boston, Mass.), comprising 100,000 sq. ft. of exhibition floor space and accommodation for 100,000 visitors, is at the disposal of the show organisers, at the back of whom are the Edison Electric Illuminating Co. This company is one of the most powerful in the States and operates electricity supply plant in 38 cities and towns. The Mechanics Building, according to the plans accompanying the prospectus, comprises three spacious floors, the whole of which will be devoted to the exhibitors at the show. On the plan there is a boiler and dynamo room, and from this it would appear that the building is lighted from an isolated plant, hardly the sort of thing that one would expect with the Edison Co., who are no doubt the local electricity authority, giving a supply. Among the items in the prospectus is one which strikes us as rather singular. This reads as follows:—"Ordinary carbon and metalised filament lamps in the usual sizes will be furnished free to exhibitors, and the management will also be prepared to sell Mazda lamps in all sizes at a fair price." Surely this is unduly penalising the metal lamp? This remark is, however, quite by the way.

The management is straining every effort to make the exhibition a popular one, and, from what we can gather, special facilities will be arranged for English exhibitors to make a display of their products. We understand that the Edison Illuminating Co. of Boston "has no intention of making a profit on the show either for itself or for any individual or group of individuals, but is undertaking work to promote the electrical industry and to familiarise the public with the possibilities and economy of electric service."

We would commend to the notice of the organisers of this exhibition our own small show (by comparison) which opens at Olympia on Sept. 23. While we do not suggest that we can in any way offer them points, at the same time we ourselves should be happy to welcome them at our own stand (No. 180) and to give them facilities for making a thorough inspection of the exhibits. It may be interesting for them to know that we hold an electrical exhibition in this country once every six years, and we especially pride ourselves on the display which we shall make at the forthcoming show.

THE OLYMPIA POSTER.

The managers of the Olympia Electrical Exhibition are making headway with the publicity work in connection with this exhibition. We understand that the bulk of the space, both in the main hall and galleries, has been let up and that

Reduced Illustration of Olympia Poster.

the show will be representative of every branch of the electrical business. Judging by a preliminary list of exhibitors which has been sent to us there should be a predominant popular note about the exhibition. This is something which we have looked for, and it is to be hoped that the response from present

and prospective users of electricity will more than exceed expectations.

We reproduce on a small scale the poster which is to be used to advertise the exhibition in all parts of the country. It is sufficiently striking to attract attention and it has the further merit of being extremely simple in design. We have not yet seen the colour scheme adopted for the poster, but doubtless this will be such as to give the exhibition the utmost possible prominence. In these days of poster advertising it is extremely difficult to hit upon some novel colour arrangement which will appear sufficiently distinctive amongst the mass of advertising matter which is usually displayed on the hoardings.

SIEMENS CORONATION ARRANGEMENTS.

Messrs. Siemens Bros. Dynamo Works inform us that they have made special arrangements to hold their offices and stores at Tyssen Street, Dalston, open during Thursday and Friday, 22nd and 23rd inst., from 9:30 a.m. until the official time of extinction of Coronation illuminations—12:30 a.m.—and are holding stocks of lamps and accessories used in connection with Coronation illuminations. Messrs. Siemens have laid themselves out to give contractors every attention either before the Coronation or on the two days and nights mentioned, and hold themselves ready as far as possible to deliver goods or render assistance, if necessary, in answer to telegraphic or telephonic requests. We may remind our readers that they can get into touch with these facilities by telephone or telegraph; telephone numbers Central 8387, 8388, 8,389; Dalston 2440 (three lines), telegraphic address "Siemodyn" London.

A section of the Dalston staff will be in attendance at 39, Upper Thames-street (telephone No. 8,270 London-wall, six lines), and, in addition, a staff of engineers will make periodical visits over the illuminations for which Messrs. Siemens are responsible. It is hoped that these arrangements will be of material assistance to contractors and others interested in Coronation work.

SIMPLEX OVENS.

intended to be as complete as the requirements of a large kitchen. In addition to the oven proper there are two boilers of one and ¾ gallons capacity respectively, a grill and a boiling ring. The oven is provided with switches for three heats and the energy consumption for these is 2,400, 1,500 and 900 watts. The grill requires 1,000 watts, the gallon boiler 1,000, and 200 watts, the ¾-gallon boiler, 750 and 150 watts and the boiling ring, 750 watts. The total capacity is therefore 6kw. The oven is supplied in two sizes, one for 10 to 12 persons and the other for six persons. Simplex conduits (Ltd.) also supply a combined cooker and grill which is made up of sheet metal with cast-iron top plate. On the right of this is arranged a grill and on the left is a ¾-gallon water boiler. This is a medium-priced cooker which should meet the requirements of a small household or flat. The grill is loaded for 1,000 watts and the boiler 750 watts, with a minimum rating of 150 watts. These cookers are worthy of the attention of electrical contractors and station men.

THE LAMPLIGHTER.

Time was when the lamplighter was looked upon in the same way as the Waverley pen—"a boon and blessing to men." Robert Louis Stevenson thus speaks of him :—

"God bless him, indeed! For the term of his twilight diligence is near at hand; and for not much longer shall we watch him speeding up the street and, at measured intervals, knocking another luminous hole in the dusk. The Greeks would have made a noble myth of such an one: how he distributed starlight, and, as soon as the need was over, recollected it; and the little bull's eye, which was his instrument, and held enough fire to kindle a whole parish, would have been fitly commemorated in the legend. Now, like all heroic tasks, his labours draw towards apotheosis and the light of victory himself shall disappear. For another advance has been effected; our tame stars are in future to come out, not one by one, but all in a body and at once. A sedate electrician somewhere in a back office touches a spring—and behold! from one end to another of the city, from east to west, there is light! *Fiat Lux* says the sedate electrician. What a spectacle, on some clear, dark nightfall, when in a moment, in the twinkling of an eye, the design of the monstrous city flashes into vision—a glittering hieroglyph many square miles in extent and where to borrow and debase an image, all the evening street lamps burst together into song! Such is the spectacle of the future. Star-rise by electricity, the most romantic flight of civilisation.

We commend this to the further consideration of our contemporaries, for we cannot think that they are unfamiliar with the original essay from which it is taken. Also, we think that the publicity managers of metal lamp firms would find texts for a good series of advertisements in the essay in question.

SUN WIRES AND CABLES.

A new catalogue is available at the offices of the Sun Electric Co. which deals with the wires and cables supplied by this firm. Cables of 600 megohm and 2,500 megohm grade are listed with the usual kinds of rubber insulation and braid or lead as a protective covering. Flexible wires for ordinary and special purposes are also priced in the list. A fly-leaf is attached to the catalogue giving prices and particulars of the Kalkos insulating boxes; we described these in a recent issue.

C. & I. Supplement No. 90.] JUNE 23, 1911. [Gratis to Subscribers.

CORONATION ILLUMINATIONS AT BRIGHTON.

In another part of this issue we publish articles describing the principal electrical features of the Brighton Corporation electricity supply. We have been furnished with particulars of a few of the principal items of the special illuminations which have been erected for the Coronation, and which will remain in position for about a month after the celebrations. Members attending the I.M.E.A. Convention will have an excellent opportunity of seeing the many artistic effects produced. The sea front will be the centre of attraction, and will probably look at its best from the extreme ends of the two piers. The entire length of the front will be illuminated with festoons of lamps, and the total distance from the eastern boundary at Black Rock to the western boundary at Hove, a matter of 3½ miles, has been treated in this manner.

The Aquarium, which occupies a central position on the front, has been outlined with electric lamps, and the terraces surrounding it have also a number of illuminated festoons. From the Aquarium itself to Grand Junction-road opposite, festoons of lights will be carried across the thoroughfare, and these will be continued along the Esplanade, crossing and re-crossing one another.

The enclosures in the Steyne, which is a pretty garden at a central point near the Aquarium, are also to be outlined with lamps. The dolphins and the three basins, together with the fountain at the top, will be lighted with fairy lamps, of which something like 500 have been used. For the promenade concerts, which are a feature of the Brighton season, the pavilion lawns are usually illuminated, and the regular scheme is to be specially elaborated by electrical designs placed at the north and south gates. On the eastern side there will be two huge letters, G and M, with a central star, each 6 ft. high and each carrying 100 electric lamps.

The electricity department have erected some 10 miles of special wiring and fixed over 10,000 lamps.

On the town hall there will be exhibited a large illuminated transparency 12 ft. by 8 ft., showing pictures of the King and Queen and the borough arms. These devices weigh nearly ½ ton, and have been carried out in cloisonné and make a particularly brilliant effect.

Volk's electric railway are arranging to illuminate all their cars, and each of the stations will be picked out with electric lamps. The effect of the lighted cars passing from point to point should be very pretty.

The Corporation has decided to bring out one or two electrically illuminated tram cars. A most elaborate scheme of lighting can be worked out on one of these vehicles, and doubtless the tramways department will have acquitted itself well in this respect.

All the principal hotels, business premises and banks have been outlined with electric lamps, and the most brilliant displays will be seen at the *Imperial*, the *Old Ship* and the *Queen's*. At the latter hotel, the King as Admiral of the fleet and the Queen in court dress have been reproduced in cloisonné designs, which are life size. The details of the uniform and orders of the King and the colours in the Queen's dress have been faithfully reproduced.

The electricity department has laid itself out specially to advise shopkeepers on electrical illumination schemes, and a special rate of 1d. per unit was fixed for all illuminations.

The programme of the I.M.E.A. Convention announces that

the meetings will be held in the Pavilion, and that the venue of the annual dinner will be the Dome. Both these buildings are of more than ordinary interest, and from an electrical point of view will be found to contain a number of exceptionally fine lighting effects. In the Dome these are obtained with an enormous electrolier, in which there are some hundreds of electric lamps. This has been suspended from the centre of the Dome and surrounded by a number of smaller fittings which harmonise with it. The Pavilion, which was at one time a Royal palace, has a number of beautiful decorations, and the original candle fittings have been adapted for electric lighting. These should be closely examined by illuminating engineers, who occasionally have an opportunity of working fittings of this character into some of their schemes. Some of the modern productions of electrical fittings makers compare rather unfavourably with these designs.

BUSH ROLLER CHAINS.

Messrs. Hans Renold, the chain experts of Manchester, and who are looked upon as chain makers par excellence, has just issued for the trade catalogue 3/35. This describes a new pattern of power chain which has recently been introduced by this enterprising firm. It is known as the bush roller chain, and is distinctive from the silent chain, which has been so largely used for mechanical work of every class. The new bush roller chain is of interest to electrical power engineers because it can be used for medium speeds on power drives where a positive form of transmission is required. The chain is offered in a number of standard sizes, which are divided into four classes—short, medium and long pitch, and extra strong. The short pitch chains are 1·25 in. and the long pitch 2·5 in. The extra strong is 1 in. The short pitch chains are suitable for normal power transmissions and for wheels having from 9 to 100 teeth. The breaking strengths vary from 1,850 lb. to 86,000 lb.

The silent chain has been designed for speeds up to 1,300 ft. per minute, and the new bush roller chain is intended for speeds from 400 ft. to 900 ft. per minute. For slow drives the block chain is employed, so that it will be seen that the new bush roller chain forms a useful intermediate type between the block and silent chains. The chain speed will naturally depend on the size of the chain and the number of teeth on the small sprocket. ½ in. pitch roller chain can be run up to a speed of 1,200 ft. per minute, and even as high as 2,000 ft. per minute under conditions where the service is intermittent and the life of the chain unimportant. The 3 in. pitch chain would not be run continuously at speeds above 400 ft. per minute. These speeds apply where the chains are used with wheels having 16 or more teeth. If smaller wheels are used the speed must be reduced. For example, with a 9-tooth wheel a 3 in. pitch chain should not be run above 200 ft. per minute, and a ½ in. pitch chain on the same wheel should not be run above 750 ft. per minute. The makers recommend that sprocket wheels should not have less than 9 teeth and not more than 70. An ordinary gear ratio is 4 or 5 to one, in which a minimum of 11 or 12 teeth will be used on the small sprocket. Where impulsive loads are driven by the chain a spring wheel is recommended to introduce a certain amount of slip. The booklet to which we refer contains a quantity of useful matter on the care of chains, and amongst these are instructions for taking out and putting in links. Engineers who are interested in the chain drive should take an early opportunity of applying for a copy of the above-mentioned booklet.

GLOVER'S 1911/1912.

Once again Glover's hardy annual in the shape of their tear-off calendar has put in an appearance. The calendar dates from July 1st, in accordance with the arrangement adopted last year for the first time. The daily slips are punched for attachment to a pair of substantial hooks which project from the front of the calendar card. Each slip is devoted to some matter of interest to cable engineers, and we must compliment the firm on the reproduction of the photographic illustrations. These have been submitted to a degree of touching up which brings out the details remarkably clearly, but at the same time the effect is not overdone. Practically every class of cable laying is represented, and many interesting pictures are reproduced. The editors must have a difficult task in selecting pictures which have not been previously published. The text matter of the calendar is mainly reproduced from the electrical journals and the Papers of the various engineering societies. There is a humorous vein running throughout the text, and this has been supplied by the band of humourists who, judging by their initials, get their living in their spare time in the electrical industry. The sketches are, if anything, above the standard of previous years, and we shall take an opportunity of reproducing one or two of these from time to time. The quotations from THE ELECTRICIAN are as numerous as ever. The item for Christmas Day is of interest. It is a sketch by Mr. H. W. Hartnell representing a jointer's tent set up next to a pole transmission line, away out on the moors. The country is covered with snow, and the jointer is endeavouring to smoke a Christmas pipe in front of a bucket fire.

We ventured a suggestion to the editors last year that the support for the calendar should be provided with a pocket into which the best of the daily slips could be dropped and kept for reference. At one time a separate pair of hooks was provided for this purpose, but this was not satisfactory. We still

think that a pocket somewhere on the calendar would hold the superlatively excellent slips. We understand that the calendar will be sent to interested engineers on receipt of business card.

EXCELLOS FOR DECK LIGHTING.

In our record of electrical practice on shipboard in the special Marine Issue which we published last year we could not instance a single case of the lighting of a ship's deck by arc lamps. The

Excello Lamp Lighting Steerage Deck of "Olympic."

Union Electric Co. has kindly furnished us with an illustration which shows an Excello lamp as used on board the new White Star liner "Olympic." We understand that this photograph was taken during the trials of the liner, and that it shows an Excello lamp as used for the general illumination of the steerage deck. It is an extremely interesting example of electric lighting, and we hope that it will establish a precedent which will be regularly followed in the future. There should not be the least difficulty in an illumination problem of this kind.

CROMPTON SPORTS.

The 22nd annual sports of the Arc Works, Chelmsford, were held on Saturday last in perfect June weather. The meeting has been marked by indifferent climatic conditions on many occasions, so that the ideal summer aspect on Saturday was greatly appreciated by competitors and visitors alike. The gathering was marked by a number of "unique" incidents quite apart from that of the weather: The Arc Works Band made its first public appearance, and under the conductorship of Mr. W. Hall (who has trained the men in the short period of six months) acquitted itself most creditably in a varied musical programme. Then for the first time an "overseas cup" was offered to the best all-round man at the sports by the staffs of the foreign department and colonial branches. The moving spirit in the presentation to the club of this handsome trophy was, we understand, Mr. Erskine, of the Australian branch, that gentleman being now in this country on a business tour. There was a record entry for the events, and the attendance of spectators was well above the average. Among the items of interest were a number of championships in the shape of silver cups which become the absolute property of holders after three

successive years, or four years in all. These championships were for the 100 yds. flat, the one mile flat, the two mile bicycle and the quarter mile flat; these events were won respectively by D. C. B. Copeland and A. G. Wells (dead heat), E. H. Barnes, A. F. Bearsby and E. H. Barnes. The last-named was also awarded the "overseas cup" referred to above, as the winner of the greatest number of events. When it is considered that Mr. Barnes figured in six important events he well deserved this trophy. At the conclusion of the sports the prizes were presented by Mrs. Clibborn, the wife of Lieut.-Col. J. Clibborn. Music, dancing and fireworks were the order of the evening. The company included Lieut.-Col. Crompton, C.B., Mr. Claud Crompton, Mr. Hew Stevenson, Mr. E. Reeves, Mr. Bernard Gibson, Mr. C. Peel and a large number of visitors from London.

1911 FREEZOR FANS.

The new list of the General Electric Co., describing their current season's fans, contains a number of interesting new types brought out in response to a considerable demand. In the aeroblade type the propeller consists of three narrow blades placed one behind the other in the same plane. The makers claim that with this blade 30 to 40 per cent. more air can be moved with the same expenditure of energy. This type of fan should be inspected. We illustrate the Freezor oscillating pattern fan, which is intended for suspension from ceilings. In this type the motor shaft is brought out from the opposite end of the fan blades, and is provided with a worm shell, which gears up to a flexible shaft at the end of which is a pinion arranged to rotate around a fixed toothed wheel. When the motor is running it is slowly made to revolve round the central support by the action of the small external shaft. The effect of this is to distribute the air evenly in the room below. We also illustrate a new pattern of box-blade fan, which has been introduced this year. This has been designed for the ventilation of large rooms, kitchens, smoking rooms, restaurants, steamships, and in fact in any position where a considerable amount of air is required to be moved. The motors are of the Witton semi-enclosed type, fitted with self-aligning and self-oiling bearings. The fan blades blow the air away from the motor, so that the latter is always on the intake side of the fan. The fan is made in sizes varying from 12 in. to 42 in. The first-mentioned will approximately move 1,000 cubic ft. of air per minute with an expenditure of 60 watts, and the latter 14,000 cubit ft. per minute with 550 watts. These fans can be supplied with the motors in a vertical position, which slightly increases the cost. They can be furnished for alternating-current or direct-current circuits.

MINE SIGNALLING.

At a recent meeting of the Manchester Geological and Mining Society, when the president, Mr. A. J. Tonge was in the chair, an interesting Paper on "Luminous Electric Mine Shaft Signalling," was read by Mr. J. C. Eadie. In bringing the new system of mine signalling to the notice of the audience, Mr. Eadie made use of a model apparatus. The object of the system is to lessen the responsibility of the engine man in the winding operations by the provision of a double check of both luminous and bell signals. By the use of the apparatus Mr. Eadie explained that a system was provided by which the bell signals were confirmed by visual signals, and the apparatus complied fully with the Home Office regulations. It had been in use for over two years in a Durham colliery and had been found to give complete satisfaction. The system was designed to afford a safe and rapid means of communication of orders from the different levels of the mines to the engine room. The system could be employed in conjunction with any existing bell system; it practically eliminated the risk of mistakes on the part of the engine men in receipt of instructions from the men in the mine. The entire process of winding men and coal from the bottom of the shaft is one which requires the utmost care, and by the use of a variety of safety devices to prevent overwinding, &c., it was possible to protect the lives of the men. By the further installation of a system of luminous shaft signals the dangers which always attach to the introduction of the human element were reduced to the lowest possible minimum. Mr. Eadie, who is on the staff of Siemens Bros. Dynamo Works at Manchester, was accorded a vote of thanks for his interesting Paper.

I.M.E.A. IFS AND QUERIES.

If the Convention at Brighton lasted a month, would the "stalwarts" stick it out?

Will the Mayor speak of electricity as being in its infancy when he welcomes the members?

Will the gas illuminations survive on a certain hotel?

If the spirits of Brighton give out, will it be permissible to swear a big M.D.?

Will Mr. Christie instal Diesels as a stand-by at North-road?

Who will miss the last train from Portsmouth?

What will the men do on Tuesday and Thursday afternoons, seeing that the ladies are so well looked after?

Who will go to Boulogne for the week-end?

Will there be a crocodile at the Aquarium?

Will B–rm–ngham or H–rr–g–t– be the meeting place of the Convention next year?

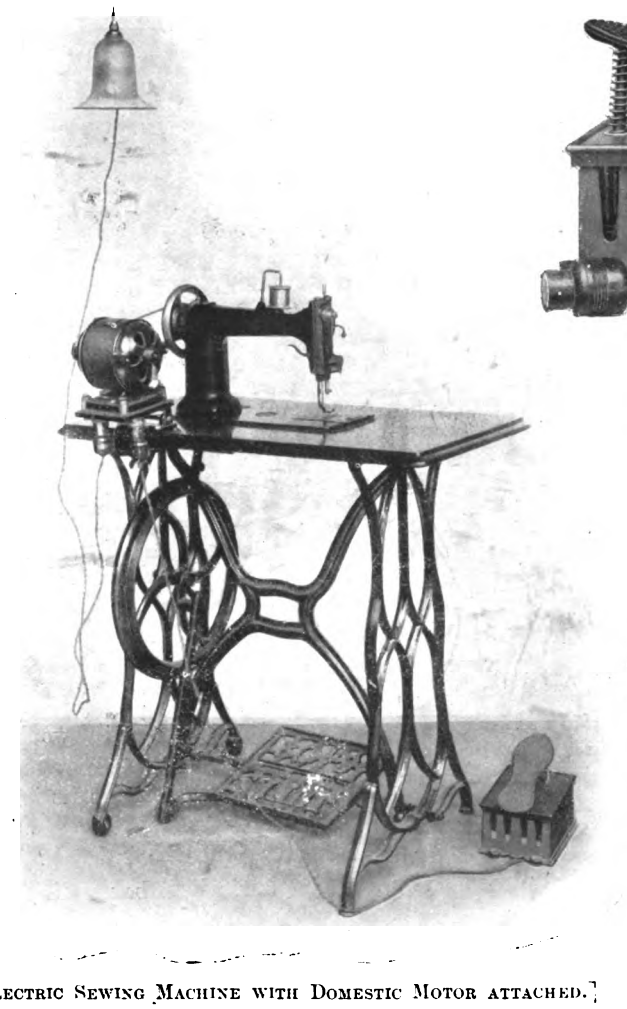
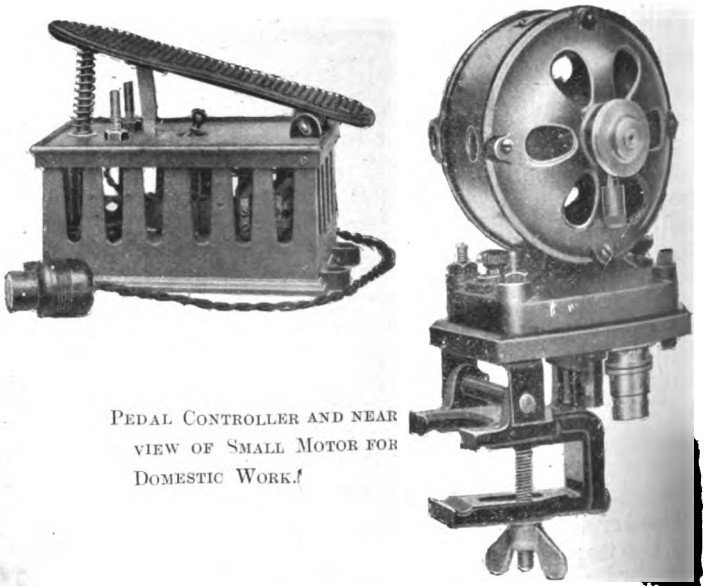
THE "DOMESTIC" MOTOR EQUIPMENT.

The use of electric power for driving sewing machines has hitherto been restricted, owing to the want of an equipment which would be suitable for any type of treadle sewing machine without modification. It has been previously necessary to employ a skilled mechanic to make an ordinary treadle sewing machine suitable for electric drive, and structural alterations have been necessary which have made it difficult to use the treadle drive when again required. Siemens Bros. Dynamo Works are now placing on the market the "Domestic" Motor Equipment, which has been designed to do away with these objections, and has the following special advantages: A lady can fix it and take it off in a few minutes. It fits all kinds of treadle machines without alteration, and the machine can be converted again to treadle drive in a few seconds.

The speed of the machine can be varied at will by means of the special foot-control switch, leaving the operator's hands free for the work. The motor is of $\frac{1}{16}$ H.P. output, and is mounted on a special table clamp, which is swivelled so that the weight of the motor automatically keeps the correct tension on the belt. The equipment includes motor, foot-control switch, two lengths of flexible cord with plug adaptors for connecting to electrical supply and switch, also special table clamp and two metal rails for fixing same to table, and the whole arrangement, as can be seen in the illustrations, is very neat and compact.



ELECTRIC SEWING MACHINE WITH DOMESTIC MOTOR ATTACHED.



PEDAL CONTROLLER AND NEAR VIEW OF SMALL MOTOR FOR DOMESTIC WORK.

REASON'S AND THE I.M.E.A.

The visit of the I.M.E.A. to Brighton will give its members a splendid opportunity to visit the works of the Reason Mfg. Co., Lewes-road, where so many specialities used in connection with central stations and electrical supply are made. The management are making arrangements to give engineers who favour them with a visit every facility for inspecting both the processes of manufacture and the finished article. A great variety of street lighting fittings will be on view, besides electrolytic meters, fuse boxes, demand indicators, time switches, &c.

C. & P. SILENT AUTO-TRANSFORMERS.

Station engineers and contractors will be interested in these nsformers, because the makers claim that special attention s been paid to the combination of very small iron losses h high full load efficiency; this ensures low voltage drop on secondary circuit between full load and no load. Great e has been exercised in manufacture, and the coils, during ding, are thoroughly impregnated with a waterproofing and ulating compound. The transformers, though ventilated, in so far as the case is concerned, can be used with satisfaction in damp situations. A feature of the terminals is the use of mica and metal in the insulation and the cable holes are bushed with porcelain to prevent abrasion of the insulation.

C. & P. AUTO-TRANSFORMER.

A 12 months' guarantee is given with C. & P. transformers, which covers the usual defects orkmanship or material, excluding, of course, bad ling, misuse, &c.

arefully prepared list (No. 102), just issued, will enable ayer to select the required type of transformer for his se. A convenient formula is included in the list whereby ansformer, the nearest to the unlisted ratios, can be selected the standard stock.

temperature rise with these transformers is low, the regulation is close and the device operates without noise. The overload capacity is 25 per cent. for two hours, a particularly generous rating. An illustration of the transformer is given herewith, and full details can be obtained from Messrs. Carney & Pearn, Nutsford Vale Works, Manchester, S.E.

THE HOADLEY CURRENT LIMITER.

This instrument consists of a laminated electromagnet, one limb of which is pivotted and, by means of a screw adjustment fitted to the end, can be moved round the pivot. The energising coil for this magnet is in series with the consumer's lamps and the magnetic circuit is completed by means of a Z-shaped armature carrying a pair of contacts dipping into two mercury cups.

On the current through the coil exceeding a predetermined limit the Z-shaped armature tends to revolve on its pivot, and in doing so lifts the contacts out of the mercury cups. The circuit is thus broken and the magnet de-energised. The contacts then fall back into the mercury cups and the cycle is repeated, producing a very decided flicker on the lights until the amount of current is reduced to such an extent that the armature is no longer attracted. The flicker may be stopped in another way, by turning the milled knob at the top of the instrument clockwise. The pivotted limb of the magnet is raised, and the air gap in the magnetic circuit increased, thus the amount of current which is necessary to create a field strong enough to attract the armature is increased, and consequently the number of lights which can be lit without causing a flicker is also increased.

This alteration can be effected by the consumer without in

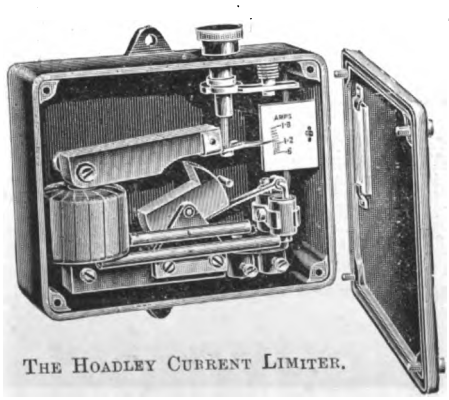
any way having to send to the supply authority. Once, however, the number of lamps or amount of current required has been raised by means of the milled knob, this cannot be again decreased until the instrument has been re-set by the supply authority.

These limiters may be used with great advantage either under a system of charging where the price per lamp is inclusive or they may be used as demand indicators where the charges are based on the "telephone system," such charges consisting of a comparatively large fixed charge and a small price per unit. These fixed charges are arrived at in several ways, either at a percentage of the ratable value of the property or on a definitive proportion of the lamps installed or in some other way; but for installations using current for lighting purposes only, by far and away the best arrangement is a current limiter, provided it possesses the advantages enumerated above, first and above all else that it can be regulated by the consumer himself. By this method not only are all the advantages of the maximum demand system of charging retained, while its disadvantages (which in England have practically killed the demand indicator system of charging) are eliminated, but additional advantages possessed by the demand indicator are to be had. Full details can be obtained from the General Electric Co., who are putting this interesting device on the market. It is made in sizes ranging from 0·3 to 1·5 amperes capacity and any voltage.



THE HOADLEY CURRENT LIMITER.

TABLES OF ELECTRIC POWER SUPPLY.

Our quarterly tables of electric power supply will be found in the centre portion of the Supplement this week. Most of the returns have been kindly brought up to date by the engineers, and our thanks are due to them for the interest which they take in this matter.

From a detailed examination of the tables we find that steady progress is being made in the connection of motors to the supply mains. At Bradford the total number of motors connected to the general supply network is 1,705, representing an aggregate of 7,463 H.P. In this district a bulk supply is also given, and to this system 220 motors are connected having a total horse-power of 2,806. At East Ham there are now 15[illegible] motors on circuit, as compared with 136 three months ago, and at Bolton an additional 27 motors have been added during the past quarter. At Salford the total brake-horse-power connected to date is 12,152, this being spread over a total of 1,0[illegible] motors. In a comparatively small town like Lincoln good progress has been made and the largest size of motor on circuit is now 100 H.P., as against 70 H.P. three months ago; the total brake-horse-power connected is now 1,785. Belfast records an exceptional rate of progress. The total number of motors has been increased from 714 to 904 and the aggregate brake-horse-power is now 6,860 as against 5,875. At Blackburn some 49 motors have been added, the total now being 7[illegible] machines on circuit. Luton has been busy with its power supply and has increased the total number of motors from 330 to 411. These aggregate 2,457 H.P. as against 2,086 H.P. Brist[illegible] also has a good return to make. There has been an increase in the number of motors of 96, and the increase in the brake-horse-power connected of 519. The Barnsley return is [illegible] made out to the 31st March of this year and the total brake-horse-power has been increased from 1,698 to 2,908.

As far as the total number of motors are concerned Liverpool has a splendid record to make, there being nearly 3,000 motors on circuit. The actual figures are 2,981, these representing a total brake-horse-power of 12,335. Birmingham runs the figures very close with a total of 2,941 motors connected, while the total brake-horse-power is more than doubled, the figure being 26,114. An interesting item in this return is one of five 720 H.P. high-tension motors; the return also shows that the approximate horse-power of other power displaced by electric motors is 15,700. This is an example which other large municipalities might do well to follow. Leeds can now boast a total of 2,482 motors connected, representing an aggregate of 14,964 H.P. Since the last return made by the Newcastle and District Electric Lighting Co., 600 H.P. of motors has been added. At Partick considerable progress has been made. The total number of motors is 315 as against 295, and the total brake-horse-power of these machines is now 3,347. The Clyde Valley Electric Power Co. show an increase of 2,200 H.P. during the past 6 months.

At Brighton, which is very much in the municipal eye at the moment, the total number of motors connected is now 5[illegible] these have an aggregate horse-power of 2,815. Sheffield has added 72 motors since last December, and these have a total brake-horse-power of 17,086. The Metropolitan Electric Supply Co., of London, now returns 1,246 motors connected, having a total brake-horse-power of 5,446. Mr. S. J. Wa[illegible] at Bury, has been making good progress. The largest [illegible] on circuit is now 100 H.P. as against 80 H.P. in the last [illegible] and 333 motors are on circuit with a total horse-power of [illegible] From Greenock we get an exceptionally good record of pro[illegible] during the past six months, the total number of motors [illegible] increased from 472 to 670.

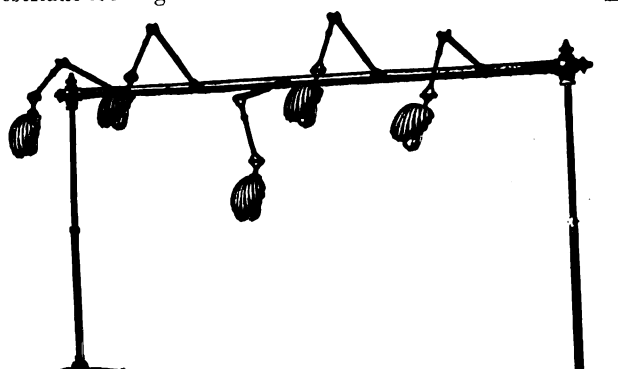
A NEW WINDOW FITTING.

Electrical contractors will be interested in a new pattern of fitting which is being introduced for the better illumination of shop windows. Its trade name is the "Constellum," and it is shown in the accompanying illustration, which practically explains the principle adopted in the fitting. The arrangement is intended to provide an undoubted want for a conveniently adjustable fitting which can be a fixture or readily portable in shop window lighting. The movable brackets are noteworthy for the knuckle joints employed. These give a wide range of movement of the bracket without the use of loose "flex" at the same time the wire inside the bracket tube is not submitted to abrasion no matter how roughly the fitting is moved or to what extent. By the use of shell reflectors the direct rays from the lamps in the brackets are shielded from the eyes of pedestrians looking into the window.



THE "CONSTELLUM" WINDOW FITTING.

The Constellum is supplied as a four-light fitting, either in enamelled steel, polished brass, bronzed brass and oxidised copper. The pillars supporting the rail to which the lamp brackets are attached are 30 in. high in the standard size of Constellum. Further details can be obtained from J. Dugdill & Co., Failsworth, who are the patentees and makers.

ALUMINIUM IN THE CHEMICAL FACTORY.

The application of aluminium to chemical work may be readily adduced from its more salient properties. The most striking physical attribute of aluminium is its lightness. Wherever large pieces of plant have to be erected or carried in difficult situations, the fact that aluminium weighs a third of iron and copper, and almost a fifth of lead, is of paramount importance. Still more important is this factor where there is question of transporting materials. The saving in weight of the containers often allows of heavier effective loads being carried; above all, where manual labour cannot be dispensed with, and where the carrying capacity of the operatives, especially of women, is limited. The high conductivity of aluminium causes it to be selected in preference to earthenware, wood, lead, tin, or iron, wherever rapid heat transference is an essential. Mechanically, aluminium is well suited to the design of chemical plant. Its great malleability allows of its being hammered into the shape of pans, drawn into the form of tubes, and rolled into sheets; whilst its tenacity is such that pressure vessels and vacuum pans can readily be made in aluminium. Though not quite as stiff as copper, aluminium is far stronger than either lead or tin.

Of the chemical properties of aluminium, the most important to the chemical engineer is the fact that aluminium salts are absolutely *non toxic*. For this reason, if for no other, it is pre-eminently the material to be used wherever possible for the manufacture, storage, and distribution of all materials destined for human consumption, such as sugar, jams, preserves, edible oils, meat extracts, milk, &c. Even in those cases where some solution of the apparatus cannot be avoided, the manufacturer may be assured that by using aluminium he is free from all danger of poison in his products. The salts of aluminium are, without exception, colourless—a factor of the utmost importance where a colourless product is required.

Aluminium shows remarkable indifference towards many organic materials, which enables it to be used very effectively for such different materials as ether and formaldehyde, citric acid, glycerine, &c. Of the common metals, aluminium is the only one which successfully resists the attack of nitric acid. As a consequence, it finds application in the nitric acid and explosives industries for such purpose as the piping of nitric and mixed acids, in the construction of acid gutters, nitrating vessels, the cages of centrifugals, &c.—*From a pamphlet of the British Aluminium Co.*

LANCING WORKSHOPS OF THE L.B. & S.C.R.

The new railway carriage works which the London, Brighton and South Coast Railway has been building at Lancing are electrically operated throughout with energy supplied from a Diesel driven power house. Two units are being installed, one of 350 kw. and the other of 250 kw., both operating at 200 revs. per min., and furnishing energy at 230 volts. The motor equipment includes one 50 H.P., one 30 H.P., 10 15 H.P., four 10 H.P. and two 5 H.P. machines. These are arranged for the group driving of modern woodworking machines. The electrical portion of the installation has been manufactured and supplied by Messrs. J. P. Hall & Co., Ltd., Blackrinding Iron Works, Oldham. The plant complies with the standard productions of this firm, and is modern in every respect. The Diesel engines are by Mirrlees Bickerton & Day and consist of one of 500 H.P. and one of 375 H.P., both of the 8-cylinder type. These engines are now undergoing test and will shortly be delivered.

ILLUMINATED CARS AT BRADFORD.

As we pointed out in our last issue, the electric tramcar is a vehicle which is conveniently adaptable to the formation of any suitable design which can be illuminated for display at night time. The Bradford Corporation set an admirable example in the recent Coronation festivities. One of their standard cars was decked out to represent a crown on a pedestal. This occupied the whole of the top deck of the car, and was elaborately treated in gold bronze, suitably lined. The band was perforated and small coloured celluloid windows were let in. When these were lighted up with lamps from behind the representation of jewels was very real.

On the lower part of the car was a red ribbon on a ground-work of royal blue, with the words "Long Live the King, 1911," in bright gold. These letters were picked out with gold coloured lamps, and a shield in gold bearing the monogram "G.R.I." in white, red, and blue lamps. On the opposite side of the car the same scheme was employed with the letters "God Save the Queen." From the ground level to the top of the Maltese Cross surmounting the car the distance was 16 ft. An elaborate scheme of illumination was adopted for the car and upwards of 1,050 lamps were introduced. The adjoining illustration shows the car in the day time. We understand that the entire scheme was designed and executed by the Bradford Corporation Tramways Department. We think it is to be congratulated on the result.

THE ELECTRICIAN COMMERCIAL AND INDUSTRIAL SUPPLEMENT.

C. & I. Supplement No. 92.] JULY 7, 1911. [Gratis to Subscribers.

THE WORKS AND PRODUCTS OF ENGINEERING INSTRUMENTS (LTD.)

The manufacture of switchgear and motor control apparatus has gradually evolved from the chaotic period in which each maker designed and built practically every class of switching apparatus according to the requirements of the particular case in view, to the stage in which each manufacturer is practically a specialist in a particular class of control apparatus. Throughout the electrical industry at the present time there are many manufacturers of switchgear, but each one has some speciality which he has made peculiarly his own and for which he has acquired a reputation. This may be said of Engineering Instruments (Ltd.), whose factory at Skerne Works, Darlington we were recently given an opportunity of inspecting. The principal products of this company comprise motor starters, controllers and regulators, metallic and liquid resistances, oil switches for both high and low voltages, and complete switch panels of both ironclad and cubicle type for central station or industrial power service.

In our walk through the shops at Skerne Works we were particularly struck with the methods which have been adopted for the standardising of each particular type of apparatus or gear. This is a desirable feature in switchgear production, because it makes for interchangeability of parts, and is an encouragement to the customer to come again. At the same time, it is an important factor in the reduction of works costs and in the cutting down to the irreducible minimum of the types of gear

manufactured. If the average consulting engineer appreciated more the importance of encouraging standardisation in switchgear manufacture he would be less exacting in his requirements of switchmakers, and would assist in the placing on the market, at reasonable rates, of reliable and satisfactory apparatus. In many cases the cost of the control gear in a motor installation is a serious item, and it may be run up to a tremendous extent if what we may call "gadgety" fitments are insisted upon.

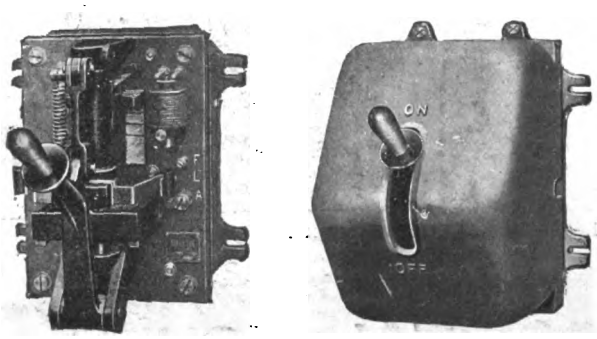

FIG. 2.—DIREKTON MOTOR STARTER, OPEN AND ENCLOSED TYPES.

The Works.—Skerne Works, Darlington, cover an area of several acres, and are devoted to the production of switchgear and stamped metal articles. The switch works comprise a roomy stores, a spacious machine fitting and assembly shop and a testing department (Fig. 1). In conjunction with these shops is a paint and enamel shop, in which certain portions of the metal supporting work are painted and stove enamelled. The equipment of machine tools includes a number of lathes, drilling, slotting, shaping and boring machines in addition to numerous metal saws. These do not call for any special comment, except that they are of modern design and are a practical assurance of accurate workmanship.

In the winding department are wound coils for the overload and no-voltage releases of the various types of circuit-breakers. The assembly benches are equipped on modern lines, and include a variety of jigs, which are used for the fitting-up of switchgear to standard centres, &c. A portion of the metal stamping works is at the disposal of the switch factory, and keeps it supplied with copper and steel stampings for contacts, springs, resistance grids, &c. The shops are light and airy, and the workmen have every convenience and comfort at all

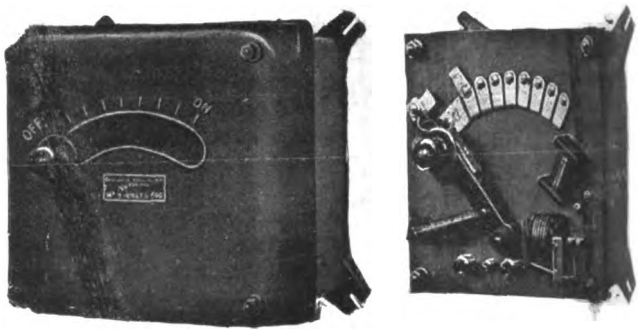

FIG. 3.—STANDARD PATTERN MOTOR STARTER.

seasons of the year. At the time of our visit we noticed a quantity of switchgear going through, particularly a number of 500-volt three-phase oil circuit-breaker control panels for colliery service. We understand that a large business in this class of apparatus is done by the firm. We also noticed a high-tension switchgear for the control of a number of generators and feeders for a textile mill installation; similarly, an iron

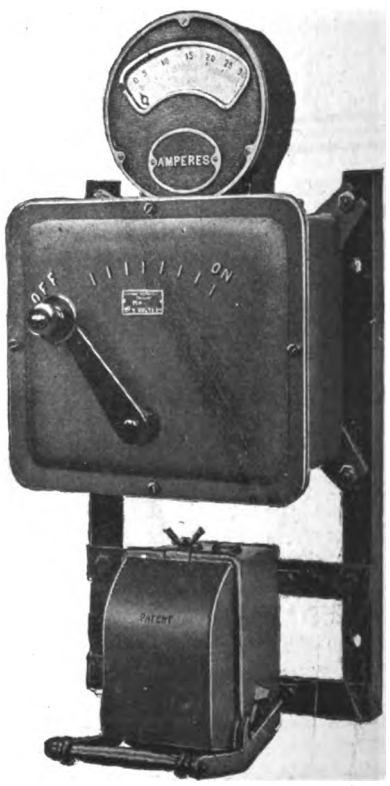

FIG. 4.—WATERTIGHT MOTOR STARTER PANEL.

enclosed high-tension cubicle type switching panel for the control of a high-voltage colliery pump. Upwards of 160 men are employed in the works.

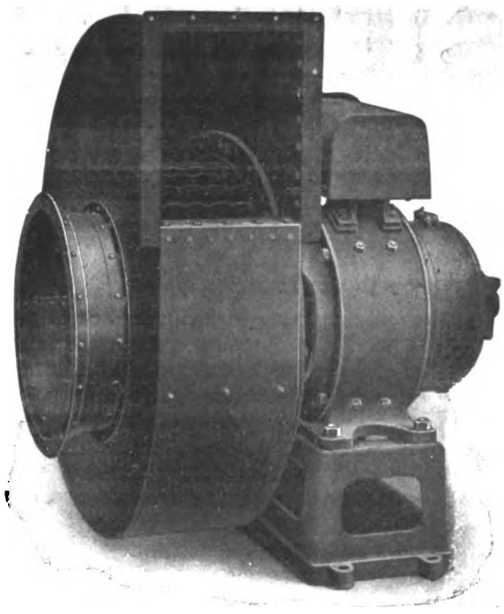
VICKERS

CENTRIFUGAL FANS

FOR VENTILATION AND FOR MECHANICAL DRAUGHT FOR BOILERS.

The fan runner is so shaped that it gives a greater volume of air per revolution than any other like fan on the market, thus enabling it to be run at a lower speed.

Economy. Efficiency.



The Electric & Ordnance Accessories Co., Ltd.,
(Proprietors: VICKERS LIMITED.)
Aston, Birmingham.

Instruments, Ltd. Before doing so we may in justice to the company state that they are among the few remaining firms who carried through a considerable amount of pioneer work on switches and switchgear, and who have furthermore witnessed the complete vindication of the principles put forward and their successful application in practice.

Direkton Motor Starters.—These motor starters have now been on the market for some considerable time, and are well known. Their great advantage is that the starting of the motor is entirely independent of the operator, and they can, therefore, be used by unskilled persons. The principle of operation is that of a spring acting against an oil-filled dashpot, the moving portion of the mechanism carrying heavy carbon brushes, which pass over the contacts and cut out resistance at a predetermined speed. Copper brushes are provided to short-circuit the carbon brushes when all the resistance is cut out. No current is, therefore, being actually carried by the carbon brushes continuously.

The starting and stopping of the motor is accomplished by pushing the handle "direct on" or pulling off. The motor starters are fitted with no-volt and overload releases, both being in operation while the motor is actually starting, giving a circuit-breaker effect, and thus entirely protecting the motor. The starters are made in the open, semi- and totally-enclosed type. Fig. 2 showing the starter in the open and semi-enclosed type respectively.

Standard Motor Starters.—The standard motor starter which has recently been introduced by the firm has several novel features, and we were particularly struck with the patent renewable contacts employed. These contacts are more readily replaceable than any which have yet come under our notice, and although held by one screw only, there is no fear of their working loose or moving in any way. Fig. 3 shows one of these starters.

All sizes of these starters are fitted with renewable contacts; complete panels are also made up consisting of standard motor

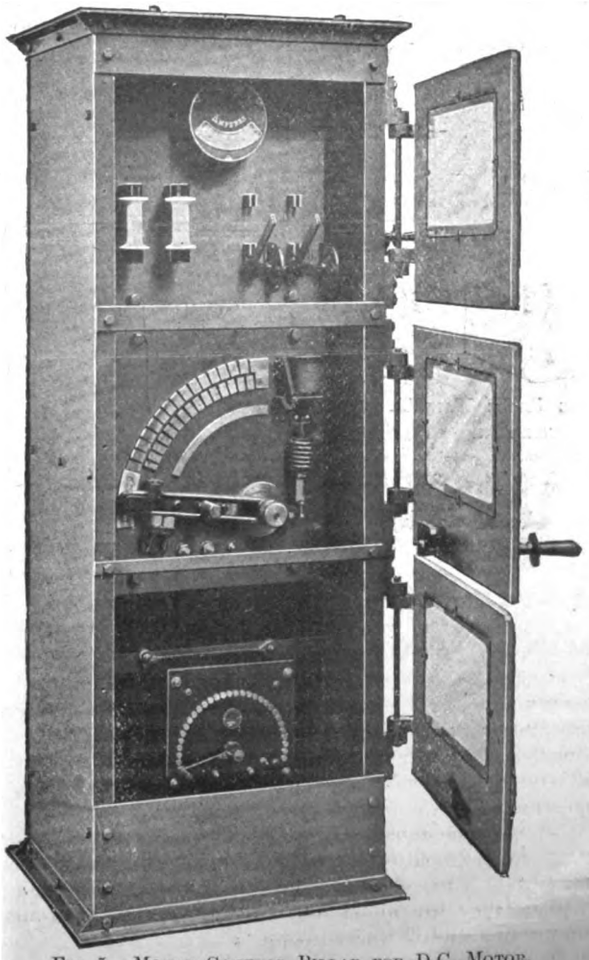


FIG. 5.—MOTOR CONTROL PILLAR FOR D.C. MOTOR.

STERLING TELEPHONES
The Sterling Telephone & Electric Co., Ltd., 200, Upper Thames Street, London, E.C. Works: Dagenham, Essex.

starters and combined watertight switch fuses, a complete panel being shown in Fig. 4.

Motor-control Pillars.—Fig. 5 illustrates a sheet steel motor-control pillar, the particular pillar illustrated being designed for controlling a 50 H.P. 500-volt continuous-current motor.

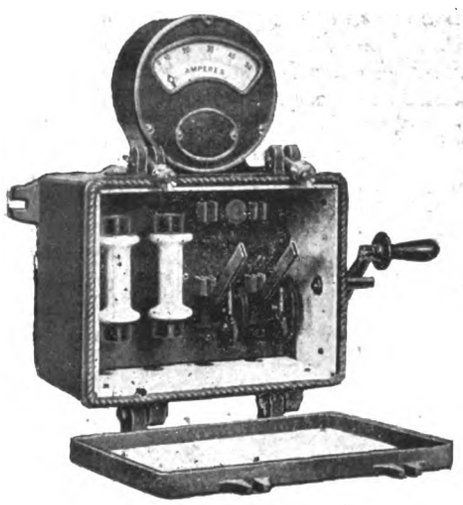

FIG. 6.—IRONCLAD SWITCH AND FUSE BOX WITH INSTRUMENT.

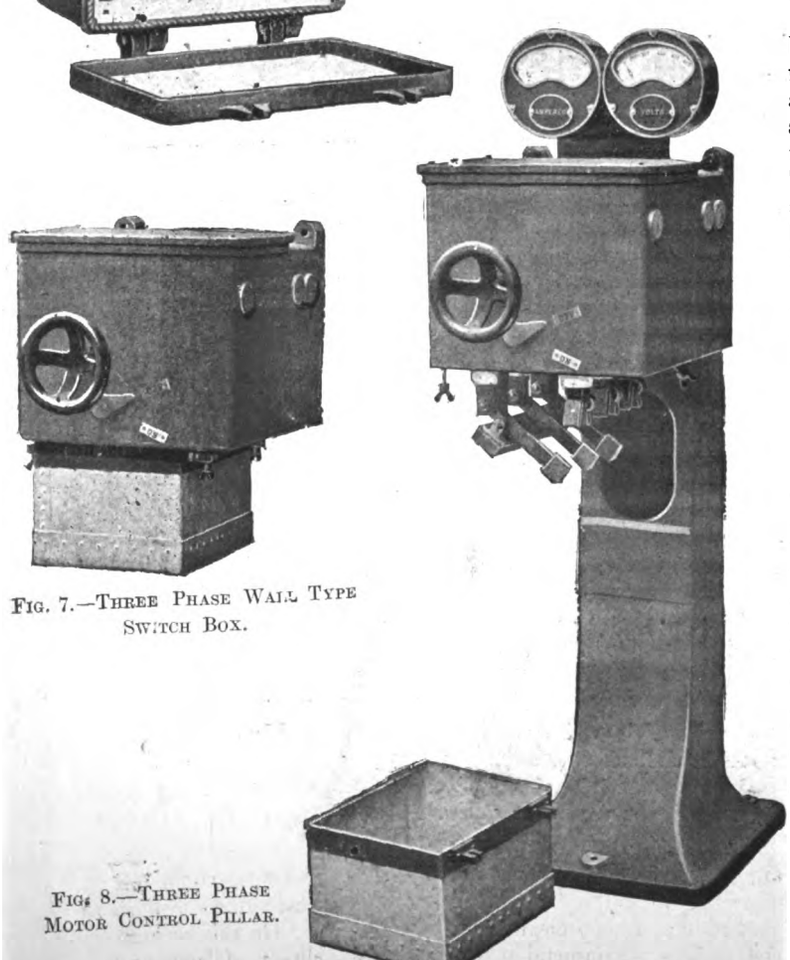

FIG. 7.—THREE PHASE WALL TYPE SWITCH BOX.

FIG. 8.—THREE PHASE MOTOR CONTROL PILLAR.

These panels are of the totally-enclosed dust-proof type, the whole design being of a substantial construction. A neat switchbox, illustrated in Fig. 6, is also one of the manufactures of the firm, these switchboxes being suitable for a current up to a maximum of 50 amperes. The boxes are fitted with double or triple-pole switches and fuses, the switches being of the quick-break knife type with operating handle outside, and the fuses of the porcelain handle tubular type.

Ammeters are also supplied with the switchboxes if required, these ammeters being bolted to the top of the switchbox, and connected between one switch and fuse internally.

Figs. 7 and 8 illustrate totally enclosed three-phase oil circuit-breakers of the wall or pillar type respectively. These circuit-breakers, which have been designed to meet the special rules for the use of electricity in mines, are of the totally-enclosed oil-immersed pattern. The oil tanks are readily removable without interfering with the gear in any way.

The circuit-breakers can be made up in the loose or fixed handle type, and fitted with overload trip coils in all three phases and no-volt release if required. The trip coils are enclosed in the top of the switch casing, covers being provided for adjusting and inspection. With this arrangement the trip coils cannot be tampered with as the covers protecting them can be sealed. Ammeters can be supplied with these circuit-breakers, and are bolted to the top of the switch casing.

The apparatus above illustrated and briefly described has been subjected to severe tests in practice and proved its general reliability in every way. Switchgear for the control of circuits and motors of every class has been installed in collieries, mines, steel works, textile mills, docks, on shipboard, &c., and under the most severe conditions met with in industrial power work. These installations are to be found in all parts of this country and the colonies, and they are a striking testimony to the excellence of the design and quality of the workmanship embodied in the apparatus.

In conclusion, we must express our thanks to Mr. E. Garside, the managing director of the works, for the facilities given us in preparing this article, and for his courtesy in showing us over the works.

HENLEY'S PAPER-INSULATED HOUSE WIRES.

In view of the discussion at the I.M.E.A. meeting at Brighton on the subject of "Modern Wiring Practice" considerable interest attaches to Henley's latest list, No. 64, which deals with paper-insulated house wires. The makers are offering two classes of this form of conductor, class YT, plain lead-covered, with twin conductors, each of high conductivity copper, insulated with paper thoroughly impregnated with a special insulating compound, the two cores being twisted together (each a different colour) and covered with a further layer of impregnated paper and sheathed with a solid drawn tube of pure lead. In the 7/20 and large sizes there are wormings between the conductors. The class YTW is the same as the above except that sizes 7/20 and smaller are served with two coats of stout compound tape, and the larger sizes are served with tarred jute yarn, and armoured with a layer of galvanised steel wires, which are left bright. The makers recommend this conductor for pressures up to 250 volts and they offer it in sizes from No. 20 to 7/16 twin conductor.

THE WEEK'S TRADE LITERATURE.

THE USCO AIR HEATER.—We commented in a previous issue on the advantages of the air heater for promoting the combustion of fuel. A new pamphlet issued by the Underfeed Stoker Co. emphasises these advantages and gives technical and engineering details of the heater and its application to boilers of every class.

AUTOMATIC FRICTION CLUTCHES.—An interesting pamphlet dealing with a new pattern of centrifugal friction clutch has been issued by Messrs. Thos. Broadbent & Sons, Huddersfield. This clutch is specially recommended by the makers for use with alternating-current motors where the starting torque is low and where it is necessary that the load shall be applied gradually to the motor. The makers give particulars of a number of applications of these clutches in the driving of hydro-extractors and textile machinery of various kinds.

THE COMPLETE SILVERTOWN PRICE LISTS.—The Indiarubber, Gutta Percha & Telegraph Works Co. (Ltd.), has issued a substantial file in which the whole of their electrical price lists is bound up. These deal with gutta-percha insulated wires and cables and jointing materials, electric bells and pushes, Silvertown instruments, standard mica tin foil condenser, telegraph and telephone line materials, dynamos and motors, and electric light cables and wires. We have had occasion to deal with these lists separately at various times in our columns, so that the general details of them will be known to our readers. We are asked by the company to state that the complete file will be forwarded to all bona-fide inquirers.

OSRAM LAMPS BY AEROPLANE.

Members of the I.M.E.A. in Brighton last week were notified of an attempt which would be made, under favourable weather conditions, to carry a consignment of Osram lamps from Worthing to Brighton by aeroplane. This novel method of transport would have been a fitting culmination to the kite advertising which the General Electric Co. carried out from the West Pier and Beach at Brighton during the Convention. But the clerk of the weather was not kindly disposed towards the passage of Osram lamps over the "filmy ocean of air," and municipal engineers and their friends had to depart disappointed.

The arrangements with the airman, Mr. H. Barber, held good, however, for some days, and on Monday last it was thought that the weather was suitable for the attempt. Some 5,000 people gathered outside Hove Marine Park, where the descent with the lamps was to be made, but they were disappointed, as Mr. Barber was for some reason delayed until it was too dark to make the attempt. On Tuesday evening there was much the same crowd, and under ideal weather conditions Mr. Barber piloted the all-British Valkyrie monoplane over from Shoreham and made a fine descent in the Marine Park. The case of Osram lamps was securely tied under the airman's seat, and was safely delivered to Messrs. Page and Miles, electrical contractors, Brighton, who had arranged to take over the consignment at the end of its novel journey. Mr. Barber then returned to Shoreham amid the enthusiastic cheers of the crowd. The idea of delivering the lamps by aeroplane originated with Mr. H. Clifford Palmer, publication manager of the General Electric Co., and we must congratulate him on the result after so many disappointments. We were present at the descent of the aeroplane, and can testify to the safe delivery of the lamps. We have since heard that not one of the large number carried was broken. The facilities for the arrival of the airman were afforded by the Hove Corporation, who kindly policed the ground, and also placed it at Mr. Palmer's disposal. The flight was made at a late hour, and several photos were taken, and we shall reproduce from these in our next issue. We may mention that Mr. Barber follows aviation in a private capacity, and the proceeds of flights of this character are devoted by him to a prize fund for the encouragement of the sport. He recently presented four Valkyrie monoplanes to the Government.

THE SMOOTHWELL ELECTRIC IRON.

A new pattern of electric iron which has been given the above trade name has been put on the market by Messrs. Siemens Brothers Dynamo Works. We understand that it is well made and inexpensive, and at the same time is a reliable article. It is well finished in nickel plate, including the face of the iron, so that it should keep clean and free from rust. On this account the makers recommend it for the most delicate of laces and light garments such as are dear to the female heart. The iron is neat in appearance, as the adjoining illustration shows, and the flexible cord has been protected by a special wire guard. The weight of this iron is 6 lb. and the energy consumption is stated to be 400 watts. Where the supply of energy is given at a penny a unit this makes the use of the iron very inexpensive.

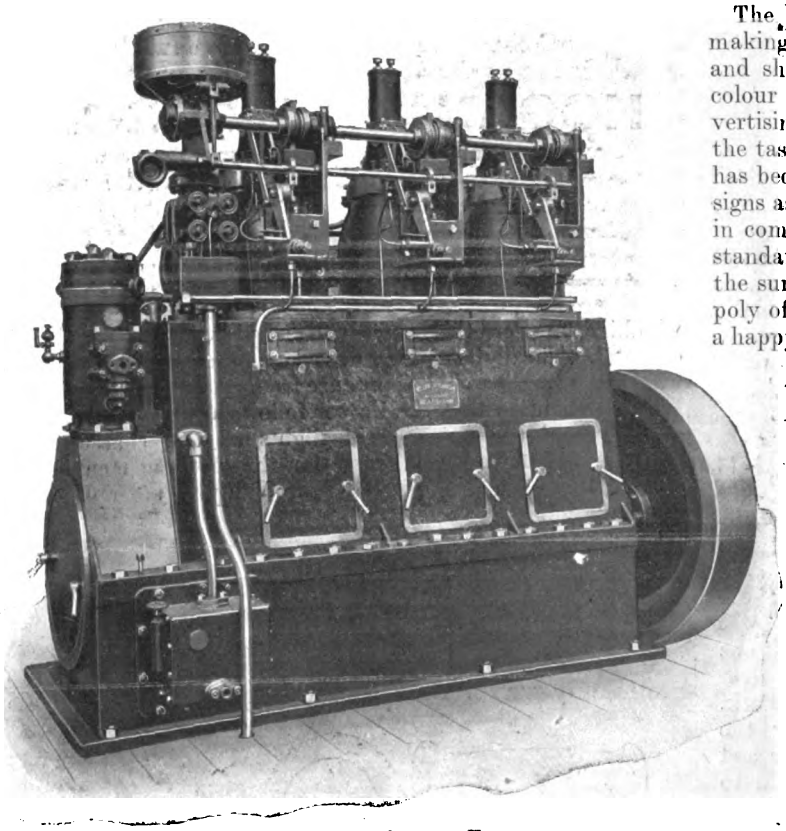
THE WILLANS TWO-STROKE DIESEL ENGINE.

In order to meet the demand for an internal combustion engine which embodies the advantages of the Diesel principle as well as those of high speed, Willans & Robinson (Ltd.) have utilised their extensive experience in the manufacture of the Willans-Diesel slow-speed oil engine and the Willans high-speed steam engine to design and produce a type of engine on quite new lines. The engine illustrated herewith has three cranks, and will develop 75 B.H.P. when running at its normal speed of 450 revs. per min. This size of engine is also built with two or four cranks, the powers being 50 or 100 B.H.P. respectively. It may be used for driving all classes of machinery, for it is equally well suited for driving electric generators, a line of shafting, agricultural machinery, centrifugal pumps, fans,



WILLANS-DIESEL TWO-STROKE ENGINE.

compressors or blowers, &c., coupled up to these either direct or by means of belts or ropes, in which latter case a suitable belt or rope pulley is provided with the engine.

The engine works on the Diesel principle, and uses cheap crude petroleum as fuel, this being ignited solely by the temperature of the air compressed in the main cylinder, where it burns slowly, power thus being imparted to the piston without any explosion, or the use of any ignition apparatus. No vaporiser is required, and the engine may be started up without any preliminary heating. It differs, however, from the ordinary type of Diesel engine, insamuch that in every four strokes which each piston makes two of these are power strokes, whereas in the ordinary type only one of the four is a power stroke. As a consequence of this, and the high speed at which the engine may be run, it is small in size, compact in form and all its parts are light. The cost of a complete installation is thus reduced to a minimum, not only as regards the engine itself and the generator or machinery it may have to drive, but also as regards the foundations, buildings and accessories; whilst at the same time the well-recognised advantages of the Diesel system are retained. These latter advantages are set out in Willans & Robinson's pamphlet dealing with their ordinary type of Willans-Diesel engine, a copy of which will be sent to those interested in the use of internal combustion engines for any purpose. The above engine was on view at the Royal Agricultural Show, Norwich, where it was running as part of Willans & Robinson's exhibit.

NOVEL SHOWCARD COMPETITION.

The appeal which the metal lamp manufacturers are now making to the public necessitates the distribution of posters and showcards which will be both distinctive in design and colour and attractive and pleasing to the public. Modern advertising has been brought to such a degree of efficiency that the task of publicity managers in the selection of good matter has become increasingly difficult. As far as we know such designs as are accepted are submitted by the regular trade artists in competition with one another. This factor ensures a high standard of excellence, because competition usually results in the survival of the fittest. Even trade artists have no monopoly of ideas. Sometimes the lay man will suddenly hit upon a happy idea which, if worked up by a professional man, will give the advertising manager exactly what he requires. This peculiarity of the public to provide spontaneously what the professional man cannot evolve by hours of thought and labour has been proved over and over again. It was particularly evident when the "Evening News" asked the public for its ideas as to a suitable poster for the London Underground Railways Co. The design selected was not only novel but it proved that the author was an artist of no mean ability.

With these preliminary remarks we will turn to the Tantalum showcard competition which Messrs. Siemens Brothers Dynamo Works (Ltd.) have just arranged. The main idea in view is to give everyone, but we may say more particularly present and prospective consumers of electricity, an opportunity of submitting to the company what they think to be a suitable showcard for the advertising of its products. The Tantalum lamp public advertising and postering has always been consistently good. The company were pioneers in this direction and their "Satisfied Consumer" poster has found its way into every corner of the world. We have from time to time reproduced illustrations of this poster in almost every language.

The general conditions of the competition are set out in an advertisement which will be found on another page of this issue, but briefly we may say that the company offer prizes of £75 and £25 for the best and second best design for a showcard to advertise to the public the merits of their Tantalum lamps. It is stated that preference will be given to designs which embody the chief features of the "Satisfied Consumer" poster, though the inclusion of this is not absolutely essential. The design must be submitted in colours on stiff card 24 in. high by 18 in. wide. One condition must be strictly observed, and that is that the designs submitted must have no political reference. The com-

pany reserve to themselves the right to accept the prize designs, the payment for which will be the prizes themselves, and further to accept and use any other submitted design on the payment of £5 per design. The designs will, of course, become the property of the company and may be copyrighted by them. Original designs will be returned, though the company will not be held responsible for loss or damage.

This novel competition is now open and the last day for receiving designs is Monday, July 31. They may be sent to Messrs. Siemens Brothers Dynamo Works (Ltd.), Tyssen-street, Dalston, London, N.E.

We hope that our readers, both professional and trade, will take an interest in this competition, because they must have a considerable fund of ideas upon which to draw for a competition of this nature. We shall be pleased to publish the names of the successful prize winners as soon as these are announced, and we understand that the company is advertising the scheme in the daily papers.

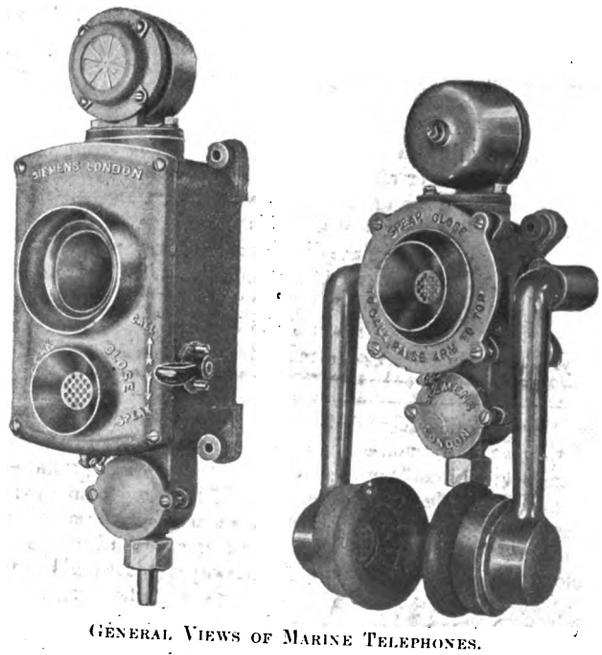
MARINE LOUD-SPEAKING 'PHONES.

The importance of telephonic communication on shipboard has long been recognised and electrical practice in the marine world have produced the loud-speaking telephone which is now a standard attachment of all modern vessels. The chief feature of the Siemens loud-speaking telephone system is that the loud tone is not obtained by the usual method of allowing large currents to pass through the microphone; this is usually a source of trouble, as it causes the carbon granules to agglomerate and thereby to reduce the volume of sound—but by the special construction of the microphone and the method of connections. The current passing through each microphone is only about 0·07 amperes. In addition, with the system of connection used, the speaking current does not pass through the source of supply as is usually the case. The passage of the speaking current through the source of supply greatly impairs the articulation. Another important point in these instruments is that the microphone and telephone are constructed in a removable capsule form, and are perfectly watertight. This is important in the case of the microphone, as the presence of moisture on the carbon granules prevents clear and loud speaking. In addition to the capsules, the cases of the instruments are also made watertight. The instruments are manufactured



General Views of Marine Telephones.

in two types, the ordinary type with fixed trumpet, and the engine room type with movable ear trumpets for particularly noisy situations. The ordinary type is also supplied mounted in a hood supported on a column for deck use, such as for docking purposes. Both types are so arranged that, without any alteration, a bell or indicator, or both, can be added. In addition, they can be connected directly in pairs, or grouped on switches or connected to an exchange board.

The instruments are arranged for working on 15-volt circuits, which can be provided either from the ship lighting mains by means of a potentiometer resistance, or by batteries. Complete installations are undertaken and all accessories, including instruments, cable, line coils, switches, exchange boards, batteries, motor-generator or resistances, to form installations of any number of instruments or any desired system of connections, can be supplied. Siemens Bros. & Co. will furnish additional particulars.
